#### 1 ABSTRACT

2

In the Netherlands, the functional approach described in the 2008 European Asphalt 3 Concrete standards was selected, specifying mixtures by their stiffness, fatigue resistance, 4 permanent deformation, moisture sensitivity and limited composition data. The 5 requirements for the functional specifications were based on the existing experience with 6 7 a large number of mixes. Since the introduction of the standards, unexpected developments like improved performance in all functional tests with increasing RAP 8 content, led to questions about the predictive quality of the laboratory determined 9 functional characteristics for field performance and the potential causes of a mis-match 10 between lab and practice. These questions led to a large, long term project in the 11 Netherlands (NL-LAB) in which the functional characteristics are determined in the 12 13 process of construction projects. They are determined on (I) material mixed and compacted in the lab, (II) mixed in the plant and compacted in the lab and (III) mixed in 14 the plant and compacted in the road. These tests will eventually provide insight in the 15 effect of mixing and compaction. The pavement sections are monitored in time, to allow 16 17 the link with pavement performance. The sections will be sampled during their service life to see changes occur in their functional properties. For the road industry, that tries to 18 guarantee pavement performance by accurate selection of materials, the possibility of 19 20 design information based on both laboratory and in situ results would be beneficial.

Two mixes for base layers with different mix compositions and amounts of RAP are analysed using formalistic expressions originating from Design Guide Level II for estimation of various performance indicators. This project uses expressions to analyse the differences between the mixes in the three cases described above. It addresses the possibility of utilizing these expressions during preliminary mix design to guide the selection of mix composition parameters towards a desired optimum.

27

#### **1 INTRODUCTION**

2

36

37

It is always a crucial point in every mix design to optimize the performance of a mix on 3 the basis of the mixture components (aggregate type, bitumen stiffness, aggregate 4 gradation). Furthermore, the increasing use of RAP in Hot Mix Asphalt (HMA) requires a 5 more detailed study of its effect on the intended performance. Certainly, laboratory tests 6 7 are crucial in this process even if they are expensive and of time consuming nature. For these reasons their number should be limited. Formalistic expressions for estimation of 8 various performance indicators could help road authorities and engineers in coming up 9 with a preliminary choice of aggregate and bitumen type for further laboratory 10 investigation. 11

At European level, the indirect tensile test (IDT) (EN 12697-23, 2003) (2) and the 12 triaxial cyclic compression test (TCCT) (EN 12697-25, 2005) (3) are two of the tests used 13 in the European Standard Specification EN for HMA mixture characterization. It is well-14 known that the mechanical response of the HMA samples is strongly related to the 15 mechanical-physical characteristics of the single components (bitumen, aggregate and 16 17 voids). Therefore, several formalistic relations for tensile stress at failure and permanent strain have been developed over the years. In general, they are based on linear regression 18 between the various mix composition parameters. Nevertheless, after appropriate 19 20 calibration, their utilization for the estimation of HMA mixture properties has become standard in engineering practice. The first step of this research was to evaluate the 21 applicability for European mixes of the formalistic expressions available for Level II 22 23 design in NCHRP 1-37A (1) on the basis of laboratory tests.

Generally, the performance of a mixture is not affected by one parameter alone. A 24 large set of mixture variables in fact influence its performance and as reported by the 25 26 Project 1-37A (1) formula, not always linearly. Also, it is well known that the properties realized in the actual pavement will vary and may differ from those found in laboratory 27 tests. In this paper the essential influences of the various composition-related factors are 28 investigated in detail using statistical and back-calculation analyses to identify the 29 significant variables to be included in the relationship between measured and back-30 31 calculated values.

The characteristics of two mixes have been determined during all the phases of design and construction (from laboratory investigation to field compaction) from construction projects on two important Dutch roads: Highway A4 and Provincial Road N345. The following cases will be discussed in this contribution:

- Case I: Lab-Lab (the specimen have been produced and compacted in the laboratory by means of gyratory compactor);
- Case II: Plant-Lab (HMA has been transported from the plant to the laboratory and there gyratory compacted);
- Case III: Field (HMA has been transported from the plant to the field and there compacted by means of roller compactor).

The variables considered in the NCHRP report (*1*) were utilized for the starting phase of the research, aiming to determine suitable coefficients for the European conditions. In a later stage, the sensitivity of all the variables was studied: some variables were considered not relevant for the case of study and new variables were added. Details about the backcalculation procedures that were developed and the verification of the reliability of the different formulae for the evaluation of ITS and permanent strain is discussed.

#### NCHRP DESIGN GUIDE

- 2
- In the NCHRP Design Guide 1-37A(1) the formula for the indirect tensile strength (ITS) is stated as:

$$TS = 7416,712 - 114,016 * V_a - 0,304 * V_a^2 - 122,592 * VFA + 0,704 * VFA^2$$
(1)  
+ 405,71 \* log(*Pen*<sub>77</sub>) - 2039,296 \* log(*A*) (1)

- 5 where:
- *ITS* = Indirect Tensile Strength at -10°C (psi);
- 7  $V_a$ = Air voids (%);
- 8 *VFA* = Voids filled with asphalt (%);
- *Pen*<sub>77</sub>= Binder penetration at 25°C (mm/10);
- 10 A = Viscosity-temperature susceptibility intercept.
- 11 The Design Guide (1) procedure requires the determination of the tensile strength at -12 10°C and a load rate of 51 mm per minute. The  $R^2$  quoted in the Design Guide for these 13 parameters is 0.62.
- 14 The Design Guide (1) also provides an expression for the viscous creep 15 compliance. It is obtained by taking into account the correlations of creep tests with 16 volumetric and mixture properties of an asphalt mix. The formula for the creep 17 compliance at time *t*, as published in the Design Guide (1), is given as:

$$D(t) = D_1 \cdot t^m \tag{2}$$

- 18 where  $D_l$ , m = creep parameters.
- 19 The expression used for  $D_1$  is:

$$\log(D_1) = -8.5241 + 0.01306 T + 0.7957 \log(V_a) + 2.0103 \log(VFA)$$
(3)  
- 1.923 log(A<sub>RTFO</sub>)

20 where:

- T = Test temperature (°F);
- $V_a = \text{Air voids (\%)};$
- *VFA* = Voids filled with asphalt (%);
- $A_{RTFO}$  = Intercept of binder Viscosity Temperature relationship for the RTFO condition.
- 26 For the *m* parameter, the expression is:

 $m = 1.168 - 0.00185 T - 0.01126 VFA + 0.00247 Pen_{77} + 0.001683 Pen_{77}^{0.4605} T$ (4) where:

- 27 where:28 7
  - T = Test temperature (°F);
  - $V_a = \text{Air voids (\%)};$
  - *VFA* = Voids filled with asphalt (%);
- 31  $Pen_{77}$  = Penetration at 77 °F =  $10^{290.5013 \sqrt{81177.288 + 257.0694 * 10^{(A+2.72973 * VTS)}}}$ 32 (mm/10);
- A =Viscosity-temperature susceptibility intercept;
- VTS = Slope of binder Viscosity Temperature relationship.
- 36 MATERIALS
- 37

35

29

30

Mixes from Highway A4 (Amsterdam-Zandvliet) near Steenbergenand and from Provincial Road N345 (Apeldoorn-Zutphen)in the Dutch network were analyzed. Aggregate type, gradation and reclaimed asphalt types and percentage were different. The A4 specimens contained 50% of reclaimed asphalt while those from N345 contained 60%. Specimens were tested in the laboratory originating from: (Case I) laboratory production and gyratory compaction, (Case II) plant production and gyratory laboratory

compaction and (Case III) plant production and field compaction. For each mixture the 1 average values of the considered variables in the back-calculation phase are reported in 2

3

6 7

8 According to the European Standard EN 12697-23 (2), the test conditions for the IDT are 15°C and a load rate of (50±2) mm/min. In this paper the ITS is expressed in MPa. The 9 triaxial cyclic compressive test has been carried out at 40 °C (104 °F) with a confinement 10 stress ( $\sigma_c$ ) of 0.05 MPa and an amplitude ( $\sigma_v$ ) of 0.2 MPa. This results in a peak load of 11 the discontinuous sinusoidal compressive stress of 0.45 MPa in accordance to the 12 European Standard EN 12697-25 (3), the principle of the applied stress signal is give in 13

Figure 1. 14

15

FIGURE 1 Schematic of the stress signal in time. 16

17

#### 18 **ITS PARAMETER DETERMINATION**

19

As shown in the previous section the formulae given by the NCHRP project 1-37A(1) are 20 composed by expressions of variables with associated multipliers. A general relationship 21 between the variables and their multipliers for the ITS is · 22

$$ITS = A_1 + A_2 * V_a + A_3 * V_a^2 + A_4 * VFA + A_5 * VFA^2 + A_6 * \log(Pen77) + A_7 \\* \log(A)$$

- where: • ITS = Indirect Tensile Strength at -10°C (psi);
- $A_1...A_7$  = multipliers; •
  - $V_a$ , VFA, log(Pen77), log(A) = physical variables. •
- 26 27

23

24

25

28

(5)

#### **Back-Calculation of Multipliers** 1

2

4

Introducing M as the matrix of physical variables (VFA, Pen77, etc.) and A the vector of 3

unknown multipliers, the ITS equation can be expressed as:  

$$[ITS] = [M] * [A]$$
(6)

$$[ITS] = [M] * [A]$$

Every row in matrix M represents a separate measurement which results in a 5 corresponding ITS value, so that it holds that: 6

$$\begin{bmatrix} ITS\\ \vdots\\ ITS \end{bmatrix} = \begin{bmatrix} 1 & V_a & V_a & VFA & VFA^2 & Log(Pen77) & \log(A)\\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots\\ 1 & V_a & V_a & VFA & VFA^2 & Log(Pen77) & \log(A) \end{bmatrix} * \begin{bmatrix} A_1\\ \vdots\\ A_7 \end{bmatrix}$$
(7)

M must be composed of a number of rows at least equal or greater than the number of 7 multipliers  $A_i$ . A total of 31 tests results were available in this study. Utilization of all 31 8 test results in the back-calculation procedure rendered the above system of equations 9 over-determined and necessitated the use of Least Squares for its solution (4). As 10 mentioned before, the formula for the ITS value vector consists of the multiplication of 11 the matrix of physical variables *M* and the multiplier vector A as: 12

$$[ITS] = [M] * [A] \tag{8}$$

Pre- and post multiplying both sides with  $([M]^{T*}[M])^{-1}[M]^{T}$  and after some mathematical 13 manipulations it results 14

$$[A] = ([M]^T * [M])^{-1} * [M]^T * [ITS]$$
(9)

which enables the determination of  $A_i$ -s on the basis of the ITS test values. 15

After obtaining the new calculated vector of ITS values it is possible and 16 necessary to make a comparison between the measured values during tests and the back-17 calculated ones. The calculation of errors is of fundamental importance for the 18 comparison between the experimental and back-calculated ITS values and especially for 19 the evaluation of the level of interdependence of the physical variables used for the 20 calculation of ITS. Computation of the error between predicted and computed ITS values 21 is important for the verification of the suitability of the multipliers  $A_i$  as determined via 22 23 the back-calculation procedure.

24

#### 25 TCCT PARAMETER DETERMINATION

26

For the analyses of the resistance to permanent deformation, the European Standard EN 27 28 12697-25 (3) provides two formulations, a linear one and an exponential function. Both depend on the number of loading cycles. In this paper the exponential form for the plastic 29 strain is adopted: 30

$$\varepsilon_N = A \cdot n^B \tag{10}$$

31 where *A* and *B* are coefficients and *n* is the cycle number.

A triaxial cyclic compressive test (TCCT) is used instead of the creep test used in the 32

33 Design Guide (1). In this study, the spirit of the Design Guide (1) formula was maintained

but the actual equation was recast to represent the results of TCCT. The Design Guide (1)34 correlation between total strain, creep stress and creep compliance in time is given by the 35

following expression: 36

$$\frac{\varepsilon(t)}{\sigma} = D_1 \cdot t^m \tag{11}$$

This equation can be transformed into its logarithmic form as: 37

$$\log(\varepsilon(t)) = \log(\sigma) + \log(D_1) + m \cdot \log(t)$$
(12)

Similarly a general relationship between the physical variables and their multipliers can 38 39 be setup for the parameter  $D_1$  in logarithmic form:

$$\log(D_1) = \beta_0 + \beta_1 \cdot T + \beta_2 \cdot \log(V_a) + \beta_3 \cdot \log(VFA) + \beta_4 \cdot \log A \tag{13}$$

5

9

- 2 T = Test temperature (°F);
- $V_a = \text{Air voids (\%)};$ 
  - *VFA* = Voids filled with asphalt.
  - *A* = Intercept of binder Viscosity Temperature relationship;
- 6  $\beta_0, \beta_1, \beta_2, \beta_3, \beta_4$ = multipliers.
- 7 For the *m* parameter, the expression is reported as:

$$m = \vartheta_0 + \vartheta_1 \cdot T + \vartheta_2 \cdot VFA + \vartheta_3 \cdot Pen_{77} + \vartheta_4 Pen_{77}^{\alpha} \cdot T$$
(14)

8 where:

•  $Pen_{77}$  = Penetration at 77 °F;

- 10  $\boldsymbol{\mathcal{G}}_{0}, \boldsymbol{\mathcal{G}}_{1}, \boldsymbol{\mathcal{G}}_{2}, \boldsymbol{\mathcal{G}}_{3}, \boldsymbol{\mathcal{G}}_{4}$ = multipliers.
- A set of modifications are made in the following to this equation to recast it in a form suitable for TCCT. The first assumption concerns the loading stress. In the TCCT a pulse load is utilized instead of a constant load. In this study, the choice is made to relate the creep stress to the maximum stress of the pulse load:

$$T = \sigma_{a,max}$$
 (15)

The second assumption is that the creep test time t can be substituted by the time required for n load cycles, each of 1 sec duration. Finally, in contrast to the Design Guide, it is assumed that Eq. 12 is suitable to describe the development of plastic strain as it progressively develops with increasing number of cycles.

Data from a total of 39 test specimens were available. As in the case of the ITS, on the basis of Eq. 13 and Eq. 14 and the available data, two systems of equations can be formulated:

$$[\log D_1] = [S] * [\beta]$$
(16)

$$[m] = [T] * [\vartheta] \tag{17}$$

22

#### 23 Back-Calculation of Multipliers

- 24
- Solution of the above two over-determined systems of equations provides the values of the  $[\beta]$  and  $[\vartheta]$  multipliers. Use of the Least Squares technique is necessary because of the over-determined nature of the systems. Following the same numerical procedure as in the case of ITS,  $[\beta]$  and  $[\vartheta]$  multipliers are determined as:

$$[\beta] = ([S]^T * [S])^{-1} * [S]^T * [\log D_1]$$
(18)

$$[\vartheta] = ([T]^T * [T])^{-1} * [T]^T * [m]$$
(19)

29 Once [ $\beta$ ] and [ $\vartheta$ ] are known, the values of  $D_1$  and *m* can be calculated as:

$$\log(D_1)_{calc} = \beta_0 + \beta_1 \cdot T + \beta_2 \cdot \log(V_a) + \beta_3 \cdot \log(VFA) + \beta_4 \cdot \log A$$
(20)

$$m_{calc} = \vartheta_0 + \vartheta_1 \cdot T + \vartheta_2 \cdot VFA + \vartheta_3 \cdot Pen_{77} + \vartheta_4 Pen_{77}^{\alpha} \cdot T$$
(21)

and the plastic strain can be determined on the basis of mix composition via Eq. 12.

# 3132 **RESULTS**

33

#### 34 Indirect Tension Test

35

39

For the indirect tension test three different combinations of mix composition variables
were analyzed. The difference between them lies in the number and type of variables that
were utilized for response prediction.

• Test case 7:

$$ITS = 22.383 + 2.740 * V_a - 0.294 * V_a^2 - 0.705 * VFA + 0.006 * VFA^2 - 3.022$$
  
\* log(Pen) + 0.897 \* log(A) (22)

1 • Test case 13:

$$ITS = 17.624 + 2.672 * V_a - 0.279 * V_a^2 - 0.633 * VFA + 0.005 * VFA^2 - 2.655$$
  
\* log(Pen) (23)

• Test case 29:

 $ITS = 26.937 - 0.107 * V_a - 0.055 * V_a^2 - 2.846 * \log(Pen) - 8.016 * Density$ (24) 3 where:

- ITS value is expressed in MPa and it refers to a test temperature of 15°C;
- $V_a$  is the specimen percentage of voids (%);
- *Pen* is the bitumen penetration at 25°C (mm/10);
- *VFA* stands for Voids Filled with Asphalt (%);
  - *Density* is the density of the specimens  $(g/cm^3)$ .

9 For each Test case, the list of coefficients of the individual physical variables is shown in

10 Table 2. All 3 sources of material samples (Case I, II, III) were individually examined.

13

From Table 2 it is clear that the calculated multipliers for mixes produced by different processes i.e. lab produced vs. plant produced vs. field produced, were different and indicate the influence of mix production and compaction on mix response. The respective *R-squared* values are for Test 7: 0.93, 0.74 and 0.92, for Test 13: 0.93, 0.74 and 0.92, for Test 29: 0.88, 0.70 and 0.87. The difference between Test case 7 and Test case 13 is the parameter A. It is clear from the comparison of the  $R^2$  for the three cases analyzed that it is not a significant parameter for the evaluation of ITS. The parameters of Eq. 22 were determined by utilizing the results from all available specimens independent of mix
 production process. The numerical values of the parameters are shown in the insert of

Figure 2. The corresponding *R-squared* is 0.76 which indicates a satisfactory prediction
reliability level for the model.

5

6 FIGURE 2 Test case 7 Measured and calculated ITS; multipliers.

7

8 From the results of Test case 7, it became apparent that the viscosity-temperature 9 susceptibility intercept had very little influence on the predictions. For this reason, in Test 10 case 13 it was ignored. All other variables were as in Test case 7. The numerical values of 11 the computed parameters are shown in the insert of Figure 3. Similarly to the previous 12 case the *R-squared* is also 0.76. From the spread of the data along the equality line it is 13 clear that the calculated coefficients are capable of predicting realistic ITS values without 14 the need to include the temperature-viscosity susceptibility intercept in the formulation.

#### 16 FIGURE 3 Test case 13 Measured and calculated ITS; multipliers.

17

18 Having removed the viscosity-temperature susceptibility intercept from the list of 19 physical variables, it was decided in Test case 29 to explore the possibility of substituting VFA with density. Among these two parameters, the latter is easier to determine and it is contained in the evaluation of the VFA. Therefore the latter was chosen and the best  $R^2$ was obtained considering a linear dependency between ITS and density. The numerical values of the computed parameters are shown in the insert of Figure 4. Similarly to the previous case the *R*-squared was also 0.76.

#### 9 Triaxial Cyclic Compression Test

10

11 For the triaxial cyclic compression test four different combinations of mix composition 12 variables were analyzed.

Test case 1: 13 •  $\log D_1 = 0.1054 \cdot T - 1.7670 \cdot \log V_a - 7.5199 \cdot \log VFA - 2.9947 \cdot \log A$ (25) $m = 0.1726 + 0.0025 \cdot V_a - 0.0008 \cdot VFA + 0.0013 \cdot Pen_{77}$ (26)14 Test case 2: •  $\log D_1 = -0.0790 \cdot T - 1.2627 \cdot \log V_a - 11.0295 \cdot \log VFA - 3.1094 \cdot \log A + 10.7454$ (27) Density  $m = 11.7994 - 0.2188 \cdot V_a - 0.0283 \cdot VFA + 0.0010 \cdot Pen_{77} - 3.6187 \cdot Density$ (28)• Test case 3: 15  $\log D_1 = -0.0756 \cdot T - 1.1903 \cdot \log V_a - 10.9344 \cdot \log VFA - 5.7066 \cdot \log A + 12.3746$ (29) $\cdot$  Density + 0.0006  $\cdot$  (Pen<sub>77</sub>  $\cdot$  R&B)  $m = 15.3469 - 0.3272 \cdot V_a - 0.0452 \cdot VFA + 0.0225 \cdot Pen_{77} - 4.2495 \cdot Density$ (30) $-0.0006 \cdot (Pen_{77} \cdot R\&B)$ 16 • Test case 4:  $\log D_1 = -0.1630 \cdot T - 0.6130 \cdot \log V_a - 8.0746 \cdot \log VFA - 0.5499 \cdot \log A + 6.8926$ (31) $\cdot$  Density + 0.0015  $\cdot$  (Pen<sub>77</sub>  $\cdot$  R&B) + 1.1463  $\cdot$  bitumen%  $m = 11.8591 - 0.2370 \cdot V_a - 0.0310 \cdot VFA + 0.0489 \cdot Pen_{77} - 2.8850 \cdot Density$ (32) $-0.0014 \cdot (Pen_{77} \cdot R\&B) - 0.1680 \cdot bitumen\%$ where: 17 18 • T is the test temperature ( $^{\circ}$ F);  $V_a$  is the specimen percentage of voids (%); 19 • *VFA* stands for Voids Filled with Asphalt (%); 20 •

- *A* is the intercept of binder Viscosity Temperature relationship;
- Density is the density of the specimens  $(g/cm^3)$ ;

- *Pen<sub>77</sub>* is the bitumen penetration at 77 °F (mm/10);
  - *R&B* is the temperature of the softening point (°F);
  - % *bitumen* is the percentage of bitumen in the specimen.

As for ITS, the difference between them lies in the number of physical variables that were tilized for response prediction. For each Test case the list of multipliers of the individual variables is shown in Table 3. All 3 sources of material samples (Case I, II, III) were examined.

*R-squared* values were calculated at three instants of time (100, 1000, 10000 seconds)
and it can be stated that the greater the time instant, the higher the *R-squared*. Table 2
reports the multipliers obtained means by the back-calculation.

In Test case 1 the variables provided from the NCHRP (1) were utilized, but for 5 Log  $D_1$  has been taken into account temperature (T) while for m the constant value (K). 6 Furthermore it has not been taken into account  $T^*Pen_{25}^{\alpha}$  because of the exponential was 7 set for the creep test conditions. For this reason also Test case 2, 3 and 4 present these 8 characteristics. The R-squared values are 0.81, 0.88 and 0.93 in Case I, 0.19, 0.47 and 9 0.77 in Case II, 0.92, 0.92 and 0.93 in Case III. Test case 2 differs respect to Test case 1 10 only for *Density*: it can be seen that only the Case II has an improvement in terms of  $\mathbb{R}^2$ , 11 with values of 0.39, 0.67 and 0.90; Case I and Case III have slightly difference than the 12 13 previous Test case. A combination of Pen<sub>77</sub>\*R&B was added in Test case 3 leaving the same variables of Test case 2. The resulting parameters do not give a significant 14

contribution. In all Cases *R-squared* values don't change. Finally, in Test case 4 the
percentage of bitumen was added to the previous Test case 3. The contribution of this
variable is relevant in Case II: *R-squared* is 0.41, 0.69 and 0.91.*R-squared* values of Case
I and Case III were similar to the Test case 3.

The calculated parameters were obtained including the total number of specimens for all Test cases. The results are reported in Figure 5, 6, 7 and 8. Compared to Case I, II and III where the *R-squared* improved with increasing number of cycles, the contribution of the total number of specimens resulted to a decrease of *R-squared* with increasing number of cycles.

11 FIGURE 5 Test case 1 Measured and calculated  $\varepsilon_N$ ; multipliers.

12

Figure 5 shows the data point distribution and the parameters calculated in the Test case 14 1. The *R*-squared value is 0.78 at 100 seconds, 0.77 at 1000 seconds and 0.73 at 10000

- 14 1. The *R* 15 seconds.
- 16

1 FIGURE 6 Test case 2 Measured and calculated  $\varepsilon_N$ ; multipliers.

3 The set of new calculated parameters (Figure 6) gives R-squared values better than the

4 Test case 1. *R-squared* is 0.84 at 100 seconds, 0.83 at 1000 seconds and 0.82 at 10000

seconds. Also it can be seen the distribution of the data points which is more clusterednear the axis origin compared to the previous Test case.

7

### 8 FIGURE 7 Test case 3 measured and calculated $\varepsilon_N$ ; multipliers.

9

Figure 7 reports the data points distribution and the new parameters calculated. A further improvement in terms of *R*-squared than Test case 2 was observed:  $R^2$  is 0.87 at 100

12 seconds, 0.86 at 1000 seconds, 0.83 at 10000 seconds.

13

#### 1 FIGURE 8 Test case 4 measured and calculated $\varepsilon_N$ ; multipliers.

#### 2

In Figure 8 the comparison between measured and calculated data and the parameters are
reported. Test case 4 gives the best result in terms of *R*-squared: 0.91 at 100 seconds,
0.89 at 1000 seconds and 0.86 at 10000 seconds.

6 7

## CONCLUSIONS

8

9 New formalistic models are proposed for a-priori determination of the indirect tensile strength and the permanent strain of AC mixtures on the basis of the mix composition 10 characteristics. Two different Asphalt Concrete mixes that fulfill the CEN standards and 11 that were produced with different production methods were used for calibration. The 12 predictions of the new equations match well with the test result. Differences were 13 observed in the compositional characteristics of the three mix production methods. These 14 15 reflected on the values of the calculated multipliers of the various physical mix composition parameters developed for mix performance prediction and characterization. 16 Analyses of more of the NL-LAB data are currently underway to improve and to validate 17 18 the models.
