ABSTRACT

Compliant mechanisms actuated by pneumatic loads are receiving increasing attention due to their direct applicability as soft robots that perform tasks using their flexible bodies. Using multiple materials to build them can further improve their performance and efficiency. Due to developments in additive manufacturing, the fabrication of multi-material soft robots is becoming a real possibility. To exploit this opportunity, there is a need for a dedicated design approach. This paper offers a systematic approach to developing such mechanisms using topology optimization. The extended SIMP scheme is employed for multi-material modeling. The design-dependent nature of the pressure load is modeled using the Darcy law with a volumetric drainage term. Flow coefficient of each element is interpolated using a smoothed Heaviside function. The obtained pressure field is converted to consistent nodal loads. The adjoint-variable approach is employed to determine the sensitivities. A robust formulation is employed, wherein a min-max optimization problem is formulated using the output displacements of the eroded and blueprint designs. Volume constraints are applied to the blueprint design, whereas the strain energy constraint is formulated with respect to the eroded design. The efficacy and success of the approach are demonstrated by designing pneumatically actuated multi-material gripper and contractor mechanisms. A numerical study confirms that multiple-material mechanisms perform relatively better than their single-material counterparts.

1 Introduction

Compliant mechanisms (CMs) perform complex tasks by using the deformation of their own body. Typically, they are actuated via constant (design-independent) input forces/loads [1,2]. Nowadays, demands for pneumatically (design-dependent loads) actuated compliant mechanisms as soft robots typically made from flexible rubber-like materials for various applications, e.g., soft gripping, force/displacement inverters/magnifiers, etc., is constantly increasing in industry and academia. Such mechanisms provide various advantages [3,4]. The performances of these mechanisms can further be enhanced when they are built using multiple materials. In addition, due to developments in additive manufacturing, the fabrication of multi-material soft robots is becoming a real possibility [5,6]. To exploit this opportunity, there is a need for a dedicated systematic design approach. The primary aim of this paper is to present a systematic approach to design such multi-material pneumatically actuated mechanisms using topology optimization.

Topology optimization (TO) is a fast-growing design technique [7, 8]. It enables the introduction and removal of solid and void regions during the structure evolution while extremizing an objective under the given physical/material constraints. In a typical structural setting, the design domain is parameterized by a set of finite elements. Each element is assigned a density/design variable $\rho \in [0, 1]$, which is assumed to be constant within the element. $\rho_i = 1$ and $\rho_i = 0$ indicate element i is filled with material (solid-state) and no material (void phase), respectively. Ideally, the optimized designs consist of elements with $\rho = 1$. However, one gets fictitious material within some elements, i.e., elements with $0 < \rho < 1$ exist in the optimized design, as the TO problem is relaxed to achieve a solution [7]. Considering more than one candidate material

within a TO setting provides a much larger design space for the optimizer to explore; thus, one can obtain optimized designs with superior performances and high efficiency.

Thomsen [9] was the first to propose a multi-material TO approach by considering the concentration and orientation of composites' fibers as design variables. Sigmund and Torquato [10] presented a multi-material TO method by extending the SIMP (Solid Isotropic Material with Penalization) formulation for designing materials with extreme thermal expansion. The number of design variables per element is the same as the candidate materials; thus, the size of the optimization problem increases with the number of materials. This scheme is also termed recursive multiphase material interpolation in [11]. Fujii et al. [12] proposed the homogenization-based multi-material method. The peak function was presented by Yin and Anathasuresh [13] for designing multi-material CMs. The technique uses only one design variable per element; however, it requires gradual parameter tuning to achieve different peaks. Chu et al. [14] presented a stress-based multi-material topology optimization for CMs. Gaynor [15] used the extended SIMP material modeling with the robust formulation for designing multi-material CMs. An ordered SIMP formulation was presented by Zuo and Saitou [16]. Sivapuram et al. [17] gave a TO method with many materials using integer programming and the extended SIMP approach. We also employ the extended SIMP formulation for multi-material modeling [10, 17] with the design-dependent pneumatic load.

Fluidic pressure loads show design-dependent behaviors as they alter the location, magnitude, and direction with the structural evolution during TO. Fig. 1a shows a schematic multi-material mechanism problem pneumatic load. A representative solution is depicted in Fig. 1b. One notices that the pressure load changes location and direction as the loading surface gets altered in the final topology. Therefore, modeling such design-dependent loads becomes challenging within a TO setting [18–22].

As pneumatically actuated mechanisms experience finite deformation, which poses several unique challenges within a TO setting [23, 24]. Further, two members of the mechanisms may also come in contact, i.e., self-contact situations may arise [25]. These challenges become more pronounced with design-dependent pressure loads, which requires a dedicated in-depth study, which is out of the scope of this paper. In this regard, we assume a small-deformation theory for the presented work.

Hammer and Olhoff [18] presented the first TO approach for load-bearing structures considering the design-dependent behavior of the pressure loads. One can find the current state-of-the-art for the existing methods wherein most are proposed for designing loadbearing structures in [19, 21, 26]. A fictitious thermal model was presented by [27], which was used in [28] for designing pressure-actuated CMs. Panganiban et al. [29] proposed a non-conforming FE-based method for the pressure-actuated CMs. de Souza and Silva [30] used the mixed displacement-pressure FEs method with a projection technique; the formulation was also used in [20] to design pressure-loaded structures. Kumar et al. [19] presented an approach using the Darcy law to design pressure-loaded structures and pressure-actuated CMs. The method is extended in [26] for generating 3D pressure-activated CMs, with the robust formulation in [31], in [32] for designing 3D pneumatic multi-material soft grippers, in [22] a 100-line MATLAB code, TOPress, for pressure loadbearing structures and in [33] with a featured-based TO. The approach uses the standard finite elements and provides consistent load sensitivities using

the adjoint-variable method. The moving isosurface threshold (MIST) method is extended for designing pressure-actuated CMs in [34] while neglecting the load sensitivity terms. It is demonstrated in [19, 22] that including the load sensitivities alters the final topologies of the optimized designs. Noting the method's efficacy, success, robustness, and generality presented in [19], we adopt and modify the approach to model the design-dependent characteristics of the fluidic pressure load herein for multiple materials.

The first method to design compliant mechanisms using TO was presented by Anathasuresh et al. [35]. They formulated and extremized a weighted objective using the mechanism's flexibility measure (e.g., output displacement) and stiffness measure (e.g., strain energy). Later, a multi-criteria objective was presented in [36]. Sigmund [37] gave a mechanical advantage maximization-based approach with appropriate input displacement and volume constraints. Typically, the CMs designed using TO suffer from single-node connections [31, 37–39]. The robust TO formulation [40] is employed herein to circumvent point connections for the multi-material CMs. Multi-material has seen minimal investigation for pressure-actuated TO, while combining stiff and compliant materials offers exciting potential. We maximize the output deformation of the mechanism as per the robust formulation. The min-max optimization problem is formulated using the output deformation of the eroded and blueprint designs. A constraint on strain energy of the eroded design is considered, whereas volume constraints are applied to the blueprint design (see Sec. 4).

In summary, the new contributions of the paper are:

1. A TO approach to design pneumatic-actuated multi-material CMs
2. Pneumatic load modeling for accounting load's design-dependent characteristics in the multi-material TO setting
3. A comparative performance study of optimized CMs with multiple materials and single material
4. Optimization of different pneumatically actuated CMs with multiple materials using the proposed method

The remainder of the paper is structured as follows. Sec. 2 provides the extended SIMP multi-material formulation. Pressure load modeling for the multi-material cases by extending the Darcy law presented in [26] is described in Sec. 3. The consistent nodal loads are also evaluated. Sec. 4 provides the topology optimization formulation in the robust TO setting. A pseudocode is provided to determine the strain energy's upper limit. Sensitive analysis for the objective and constraints is performed. Numerical results and discussions are provided in Sec. 5. Two- and three-material pneumatically actuated multiple material gripper and contractor mechanisms for different volume fractions are optimized. Lastly, concluding remarks are noted in Sec. 6.

2 Multi-material modeling

The introduction section introduces some of the existing multi-material models for TO; the readers may refer to Sivapuram et al. [17] for a comprehensive list and description. By confining ourselves to density-based TO formulation, we use the extended SIMP approach for multi-material modeling. One writes the modified SIMP for a two-phase (solid and void), i.e., for one material TO as

$$E_i = E_v + \bar{\rho}_i^p (E_1 - E_v) = (1 - \bar{\rho}_i^p) E_v + \bar{\rho}_i^p E_1, \quad (1)$$

FIGURE 1: A schematic diagram for a pressure-driven multi-material compliant mechanism. (a) Design domain. Pressure load is indicated via a set of arrows. Fixed boundary conditions are also depicted. (b) A representative solution. $M_i |_{i=1, 2, 3, 4}$ are the candidate materials. One notices that with design changes the pressure load moves to a new position; thus, its magnitude, direction, and location get altered. Note here we depict only the initial and final pressure loading surfaces in (a) and (b), respectively.

where E_1 is Young's modulus of the given material, whereas elastic constant $E_v = 10^{-6} \times E_1$ is assigned to the void elements to avoid the singularity of the structural stiffness matrix during finite element analysis [7]. p , the SIMP penalty parameter, encourages optimization to 0-1 solutions. $\bar{\rho}_i$ is the physical or projected design variable for element i , which is defined herein as

$$\bar{\rho}_i = \frac{\tanh(\beta\eta) + \tanh(\beta(\bar{\rho}_i - \eta))}{\tanh(\beta\eta) + \tanh(\beta(1 - \eta))}, \quad (2)$$

with steepness parameter $\beta \in [0, \infty)$ and η determines the transition point. For all practical purposes, β varies from 1 to a finite number, β_{\max} using a continuation scheme. $\bar{\rho}_i$, the filtered design variable [41], is obtained from the actual density variable as

$$\bar{\rho}_i = \frac{\sum_{j=1}^{Nel} v_j \rho_j w(\mathbf{x}_j)}{\sum_{j=1}^{Nel} v_j w(\mathbf{x}_j)}, \quad (3)$$

where Nel is the total number of FEs used to parameterize the design domain. The volume of element j is indicated by v_j . $w(\mathbf{x}_j) = \max\left(0, 1 - \frac{\|\mathbf{x}_i - \mathbf{x}_j\|}{r_{\text{fill}}}\right)$, is the weight function, wherein $\|(\cdot)\|$ is a Euclidean distance between centroids \mathbf{x}_i and \mathbf{x}_j of elements i and j , respectively. r_{fill} indicates the filter radius.

One can extend the modified SIMP (Eq. 1) scheme for the two-material, i.e., three-phase (material 1, material 2 and void) cases as [17]

$$E_i = (1 - \bar{\rho}_{i1}^p)E_v + \bar{\rho}_{i1}^p \left((1 - \bar{\rho}_{i2}^p)E_1 + \bar{\rho}_{i2}^p E_2 \right), \quad (4)$$

where E_1 and E_2 are Young's moduli of material 1 and material 2, respectively. $E_v = 10^{-6} \times \min(E_1, E_2)$. Note now element i is assigned two design variables $\{\rho_{i1}, \rho_{i2}\}$. The corresponding physical, $\{\bar{\rho}_{i1}, \bar{\rho}_{i2}\}$, and filtered variables, $\{\bar{\rho}_i, \bar{\rho}_{i2}\}$, can be determined using Eq. 2 and

Eq. 3, respectively. $\bar{\rho}_{i1} = 1$ gives the solid state, whereas $\bar{\rho}_{i1} = 0$ indicates the void phase of element i . $\bar{\rho}_{i1} = 1$ and $\bar{\rho}_{i2} = 0$ imply material 1, whereas $\bar{\rho}_{i1} = 1$ and $\bar{\rho}_{i2} = 1$ give material 2. Thus, $\bar{\rho}_{i1}$ and $\bar{\rho}_{i2}$ are termed topology and material variables, respectively. Likewise, one writes the extended SIMP scheme for three-material/four-phase cases as

$$E_i = (1 - \bar{\rho}_{i1}^p)E_v + \bar{\rho}_{i1}^p \left((1 - \bar{\rho}_{i2}^p)E_1 + \bar{\rho}_{i2}^p \left((1 - \bar{\rho}_{i3}^p)E_2 + \bar{\rho}_{i3}^p E_3 \right) \right), \quad (5)$$

where $E_v = 10^{-6} \times \min(E_1, E_2, E_3)$. $E_i |_{i=1, 2, 3}$, are Young's moduli of material i . $\{\bar{\rho}_{i1}, \bar{\rho}_{i2}, \bar{\rho}_{i3}\} = \{1, 0, 0\}$, $\{\bar{\rho}_{i1}, \bar{\rho}_{i2}, \bar{\rho}_{i3}\} = \{1, 1, 0\}$ and $\{\bar{\rho}_{i1}, \bar{\rho}_{i2}, \bar{\rho}_{i3}\} = \{1, 1, 1\}$ give material 1, material 2 and material 3, respectively. One can readily write the extended SIMP formulation for m candidate materials [17]. For m candidate materials, each element in the parameterized domain is assigned m design variables.

3 Pressure load modeling

This section extends the pressure load modeling approach presented in [19] to the multi-material cases. For a detailed overview, the readers can refer to [19, 26]. Ideally, elements achieve solid or void states at the final stage of TO. However, elements can be considered porous in the beginning stage of optimization. Moreover, we have known pressure differences from the given pressure boundary conditions. Therefore, as proposed in [19], the Darcy law is used to model the pressure load, wherein the Darcy flux is defined as

$$\mathbf{q} = -\frac{\kappa}{\mu} \nabla p = -K(\bar{\rho}) \nabla p, \quad (6)$$

where κ , μ , and ∇p are the permeability of the medium, the fluid viscosity, and the pressure gradient. $K(\bar{\rho})$ is called the flow coefficient, which is defined for element i in a multi-material setting as

$$K(\bar{\rho}_i) = K_v (1 - (1 - \epsilon) \mathcal{H}(\bar{\rho}_{i1}, \beta_\kappa, \eta_\kappa)), \quad (7)$$

where $\mathcal{H}(\bar{\rho}_{i1}, \beta_k, \eta_k) = \frac{\tanh(\beta_k \eta_k) + \tanh(\beta_k (\bar{\rho}_{i1} - \eta_k))}{\tanh(\beta_k \eta_k) + \tanh(\beta_k (1 - \eta_k))}$. $\epsilon = \frac{K_s}{K_v}$, where K_s and K_v are the flow coefficient for the solid and void phases, respectively. $\{\eta_k, \beta_k\}$ are the flow parameters [19]. The flow coefficient does not differentiate between different materials, as any candidate material implies a solid phase. That means that the flow coefficient is only related to the topology variable, i.e., $\bar{\rho}_{i1}$ as written in Eq. 7.

Per [19, 26], to achieve a realistic pressure drop, a volumetric drainage term, $Q_{\text{drain}} = -D(\bar{\rho}_i)(p - p_{\text{ext}})$ is included in the Darcy law (Eq. 6). $D(\bar{\rho}_i)$ is also defined using a Heaviside function [19]. p_{ext} , the external pressure, is assumed to be zero. The final balanced equation using the finite element method for the Darcy law with the drainage term is [19, 26]

$$\mathbf{A}\mathbf{p} = \mathbf{0}, \quad (8)$$

where \mathbf{A} and \mathbf{p} are the global flow matrix and pressure vector respectively. The final pressure field is converted to the consistent nodal forces using

$$\mathbf{F} = -\mathbf{T}\mathbf{p}, \quad (9)$$

where \mathbf{T} and \mathbf{F} are the global transformation matrix and force vector, respectively.

4 Topology optimization formulation

In this section, we provide the optimization problem formulation and sensitivity analysis. We use the robust formulation [40] with the eroded $\bar{\rho}_e$ and blueprint $\bar{\rho}_b$ variables. One replaces η by $0.5 + \Delta\eta$ and 0.5 in Eq. 2 for evaluating the eroded and blueprint variables, respectively. $\Delta\eta \in [0, 0.5]$ is a user-defined parameter. A non-smooth min-max optimization problem is formulated and solved using the method of moving asymptotes (MMA, cf. [42]). We consider the output displacements of the eroded and blueprint (intermediate) designs within the optimization formulation. The volume constraint is applied to the blueprint designs, indicating that the optimized mechanisms are only robust with respect to over-etching [31, 40].

4.1 Optimization problem

In the robust formulation setting, the optimization problem for the pressure-driven multi-material CMs can be written as:

$$\left. \begin{aligned} \min : \quad & f_0 = \max_r u_r^{\text{out}} = \max_r \{\mathbf{I}^\top \mathbf{u}_r\} |_{r=e,b} \\ \text{such that:} \quad & {}^1 \lambda_r : \mathbf{A}_r \mathbf{p}_r = \mathbf{0} \\ & {}^2 \lambda_r : \mathbf{K}_r \mathbf{u}_r = \mathbf{F}_r = -\mathbf{T}\mathbf{p}_r \\ & \Lambda_b^q : \text{Volume constraints on blueprint design} \\ & \Lambda_e : g_2 = \frac{SE^e}{SE^*} \leq 1 \\ & 0 \leq \rho_i \leq 1 \quad \forall i \end{aligned} \right\}, \quad (10)$$

where $r = e, b$ indicates the eroded and intermediate/blueprint designs, respectively [31, 40]. \mathbf{K}_r and \mathbf{u}_r are the global stiffness matrix and global displacement vector, respectively. u_r^{out} is the output deformation of the mechanisms in the given direction. \mathbf{I} is a vector with all zeros except the entry corresponding to the output degree of freedom, which is set to one. SE^* is the desired strain energy of the multi-material mechanisms for the eroded design. SE^e denotes the strain energy of the eroded mechanism. Instead of applying material volume constraints using variable-inseparable expressions [10], we use a linear form of that. ${}^i \lambda_r |_{i=1,2}$, Λ_b^q and Λ_e are the Lagrange multipliers, where q indicates the

number of volume constraints. The volume constraints for the blueprint design for three-phase cases are noted below ($q = 2$):

$$\sum_{i=1}^{Nel} v_i \bar{\rho}_{i1} \leq (v_{f1} + v_{f2}) \sum_{i=1}^{Nel} v_i, \quad \sum_{i=1}^{Nel} v_i \bar{\rho}_{i2} \leq v_{f2} \sum_{i=1}^{Nel} v_i. \quad (11)$$

The first volume constraint limits the material 1 and material 2, whereas the second limits the amount of material 2. Likewise, for the three-material cases, the volume constraints are ($q = 2$):

$$\begin{aligned} \sum_{i=1}^{Nel} v_i \bar{\rho}_{i1} &\leq (v_{f1} + v_{f2} + v_{f3}) \sum_{i=1}^{Nel} v_i, \\ \sum_{i=1}^{Nel} v_i \bar{\rho}_{i2} &\leq v_{f2} \sum_{i=1}^{Nel} v_i, \quad \sum_{i=1}^{Nel} v_i \bar{\rho}_{i3} \leq v_{f3} \sum_{i=1}^{Nel} v_i, \end{aligned} \quad (12)$$

where v_{f1} , v_{f2} and v_{f3} are volume fraction for material 1, material 2 and material 3, respectively. v_i represents volume of element i .

To define g_2 (Eq. 10), one needs to provide the upper limit, i.e., SE^* . We decide SE^* herein at the initial stage of optimization, i.e., at the first loop of the optimization. The idea is that we should get a realizable load-sustaining design with high performance. The pseudo-code for finding SE^* and defining g_2 is given below:

Algorithm 1 Calculation of SE^* and g_2 formulation

```

Require:  $loop, \mathbf{u}_e, \mathbf{K}_e, SE^e = \frac{1}{2} \mathbf{u}_e^\top \mathbf{K}_e \mathbf{u}_e$ 
if  $loop == 1$  then
  if  $SE^e - \lfloor SE \rfloor \leq 0.5$  then
     $SE^* = \lfloor SE^e \rfloor$ 
  else
     $SE^* = \lfloor SE^e \rfloor + 0.5$ 
  end if
end if
 $g_2 = \frac{SE^e}{SE^*} \leq 1$ 

```

where $\lfloor SE^e \rfloor$ indicates the greatest integer of SE^e .

4.2 Sensitivity analysis

The optimization problem in Eq. 10 is solved using a gradient-based optimizer, the method of moving asymptotes (MMA) [42]. Thus, the derivatives of the objective and constraints with respect to the design variables are needed, which are obtained herein using the adjoint-variable method herein. One writes the augmented performance ϕ for the objective function as

$$\phi = f_0 + {}^1 \lambda_r^\top (\mathbf{A}_r \mathbf{p}_r) + {}^2 \lambda_r^\top (\mathbf{K}_r \mathbf{u}_r + \mathbf{T}\mathbf{p}_r), \quad (13)$$

Differentiating Eq. 13 with respect to the physical design variable $\bar{\rho}_r$, yields

$$\begin{aligned} \frac{d\phi}{d\bar{\rho}_r} &= \frac{\partial f_0}{\partial \bar{\rho}_r} + \frac{\partial f_0}{\partial \mathbf{u}_r} \frac{\partial \mathbf{u}_r}{\partial \bar{\rho}_r} + {}^1\lambda_r^\top \left(\frac{\partial \mathbf{A}_r}{\partial \bar{\rho}_r} \mathbf{p}_r \right) + {}^1\lambda_r^\top \left(\mathbf{A}_r \frac{\partial \mathbf{p}_r}{\partial \bar{\rho}_r} \right) \\ &\quad + {}^2\lambda_r^\top \left(\frac{\partial \mathbf{K}_r}{\partial \bar{\rho}_r} \mathbf{u}_r + \mathbf{K}_r \frac{\partial \mathbf{u}_r}{\partial \bar{\rho}_r} \right) + {}^2\lambda_r^\top \left(\frac{\partial \mathbf{T}}{\partial \bar{\rho}_r} \mathbf{p}_r + \mathbf{T} \frac{\partial \mathbf{p}_r}{\partial \bar{\rho}_r} \right) \\ &= \frac{\partial f_0}{\partial \bar{\rho}_r} + {}^2\lambda_r^\top \left(\frac{\partial \mathbf{K}_r}{\partial \bar{\rho}_r} \mathbf{u}_r \right) + {}^1\lambda_r^\top \left(\frac{\partial \mathbf{A}_r}{\partial \bar{\rho}_r} \mathbf{p}_r \right) \\ &\quad + \underbrace{\left(\mathbf{I}^\top + {}^2\lambda_r^\top \mathbf{K}_r \right) \frac{\partial \mathbf{u}_r}{\partial \bar{\rho}_r}}_{\Theta_1} + \underbrace{\left({}^1\lambda_r^\top \mathbf{A}_r + {}^2\lambda_r^\top \mathbf{T} \right) \frac{\partial \mathbf{p}_r}{\partial \bar{\rho}_r}}_{\Theta_2}. \end{aligned} \quad (14)$$

Using the fundamentals of the adjoint-variable method, we choose ${}^1\lambda_r$ and ${}^2\lambda_r$ such that $\Theta_1 = 0$ and $\Theta_2 = 0$, which give

$${}^2\lambda_r^\top = -\mathbf{I}^\top \mathbf{K}_r^{-1}, \quad {}^1\lambda_r^\top = -{}^2\lambda_r^\top \mathbf{T} \mathbf{A}_r^{-1} = \mathbf{I}^\top \mathbf{K}_r^{-1} \mathbf{T} \mathbf{A}_r^{-1}, \quad (15)$$

and, noting that, $\frac{\partial f_0}{\partial \bar{\rho}_r} = 0$, one gets

$$\frac{d\phi}{d\bar{\rho}_r} = -\mathbf{I}^\top \mathbf{K}_r^{-1} \frac{\partial \mathbf{K}_r}{\partial \bar{\rho}_r} \mathbf{u}_r + \underbrace{\mathbf{I}^\top \mathbf{K}_r^{-1} \mathbf{T} \mathbf{A}_r^{-1} \frac{\partial \mathbf{A}_r}{\partial \bar{\rho}_r} \mathbf{p}_r}_{\text{Load sensitivities}}. \quad (16)$$

Likewise, following the above steps, one finds the derivatives of g_2 (Eq. 10) with respect to the physical variables as

$$\frac{dg_2}{d\bar{\rho}_r} = \frac{-\frac{1}{2} \mathbf{u}_r^\top \frac{\partial \mathbf{K}_r}{\partial \bar{\rho}_r} \mathbf{u}_r + \mathbf{u}_r^\top \mathbf{T} \mathbf{A}_r^{-1} \frac{\partial \mathbf{A}_r}{\partial \bar{\rho}_r} \mathbf{p}_r}{SE^*}, \quad (17)$$

Now, one uses the chain rule to determine the derivatives of the objective and constraints with respect to the design variable. Say, f is a representative function for the objective and constraints; then the chain rule can be written as

$$\frac{df}{d\bar{\rho}_r} = \frac{df}{d\bar{\rho}_r} \frac{d\bar{\rho}_r}{d\bar{\rho}_r} \frac{d\bar{\rho}_r}{d\bar{\rho}_r}. \quad (18)$$

With all ingredients discussed above, we next present numerical examples and discussions.

5 Numerical examples and discussions

This section presents pressure-actuated multi-material gripper and contractor CMs to demonstrate the efficacy of the proposed design approach and to explore the large design space offered by multi-material topology optimization for this problem. The symmetric half-design domains are depicted in Fig. 2. $L_x = 0.2$ m and $L_y = 0.1$ m are taken, where L_x and L_y indicate the dimension of the mechanisms in the x - and y -directions, respectively. The displacement and symmetry boundary conditions are displayed in the figure. The gripper mechanism is actuated from the left side, whereas the contractor mechanism is activated from both the left and right sides. To facilitate gripping of a workpiece with spring constant $k_{ss} = 5 \times 10^4$ N m⁻¹, a void area of size $\frac{L_x}{5} \times \frac{L_y}{5}$ and a solid region of area $\frac{L_x}{5} \times \frac{L_y}{50}$ are considered. At the fixed boundary conditions, non-design solid regions with dimension $\frac{L_x}{20} \times \frac{L_y}{20}$ are

considered (Fig. 2).

The applied input (excess) pressure load is set to 1 bar (Fig. 2). 0 bar pressure is set to the remaining edges excluding the symmetric ones. $N_{ex} \times N_{ey} = 200 \times 100$ elements are used to parameterize the gripper design, whereas $N_{ex} \times N_{ey} = 100 \times 100$ elements are taken to describe the one-quarter of the contractor design domain. N_{ex} and N_{ey} represent the number of the bi-linear quadrilateral elements in x - and y -directions, respectively. Filter radius, $r_{min} = 8.4 \times \min(\frac{L_x}{N_{ex}}, \frac{L_y}{N_{ey}})$ is set. Poisson's ratio $\nu = 0.4$ is used with plane-stress assumptions. The out-of-plane thickness is set to 0.01 m. $\{\beta_k, \eta_k\} = \{\beta_k, \eta_k\} = \{10, 0.1\}$ is taken. The external move limit for the MMA optimizer is set to 0.1. The maximum number of MMA iterations is set to 400. For the projection filter (Eq. 2), β is updated from 1 to 128 in a continuation manner wherein β is doubled after every 50 MMA iterations, and once it gets to 128, it remains so for the remaining iterations.

5.1 Two-material mechanisms

Herein two candidate materials with $E_1 = 1 \times 10^7$ N m⁻² and $E_2 = 1 \times 10^8$ N m⁻² are considered for designing pneumatic-activated gripper and contractor mechanisms. $E_v = 1 \times 10^{-6} \times \min(E_1, E_2)$. $\nu_{f1} = 0.2$ and $\nu_{f2} = 0.1$ are considered for the gripper mechanism, whereas $\nu_{f1} = 0.1$ and $\nu_{f2} = 0.1$ are set for the contractor mechanism. $\Delta\eta$ [31,40] for the gripper and contractor mechanisms are set to 0.05 and 0.15, respectively.

The symmetric half results are shown in Fig. 3a and Fig. 4a for the gripper and contractor mechanisms, respectively. Their complete parts (undeformed) are obtained by suitably transforming the symmetric half-optimized mechanisms and are depicted in Fig. 3b and Fig. 4b, respectively. The working of these mechanisms is depicted by using their deformed profiles in Fig. 3c and Fig. 4c, respectively. The output deformation for the gripper and contractor mechanisms in the desired directions are noted 5.9 mm and 2.8 mm, respectively. The objective and volume constraints convergence curves for the gripper mechanism are depicted in Fig. 5. The steps in the objective convergence plot (Fig. 5a) are due to β updation. The volume constraints are satisfied and remain active at the end of the optimization. Both materials constitute the pressure loading boundary.

5.2 Three-material mechanisms

In this section, the mechanisms are designed using three candidate designs. $E_1 = 1 \times 10^7$ N m⁻², $E_2 = 0.5 \times 10^8$ N m⁻² and $E_3 = 1 \times 10^8$ N m⁻² are chosen. $E_v = 1 \times 10^{-6} \times \min(E_1, E_2, E_3)$. $\nu_{f1} = 0.1$, $\nu_{f2} = 0.1$ and $\nu_{f3} = 0.05$ are considered for mechanisms. $\Delta\eta$ [31,40] for the mechanisms are set to 0.01.

The optimized symmetric half results are displayed in Fig. 6a and Fig. 7a for the gripper and contractor mechanisms, respectively. The fully optimized results with the final pressure field for the gripper and contractor mechanisms are shown in Fig. 6b and Fig. 7b, respectively. Fig. 6c and Fig. 7c demonstrate the deformed profiles of the gripper and contractor mechanisms, respectively. One can note that the members of the mechanisms can come in contact, i.e., self-contact situation [25,31], if higher pressure loads are applied. The obtained output deformations in the desired directions for the gripper and contractor mechanisms are 8.2 mm and 4.0 mm, respectively.

FIGURE 2: Symmetric half-design domains for the mechanisms. (a) Gripper design domain and (b) Contractor design domain. $L_x = 0.2\text{ m}$ and $L_y = 0.1\text{ m}$, where L_x and L_y are the dimensions in x - and y -directions, respectively. The pneumatic input load is applied from the left edge of the gripper domain, whereas it is applied from the left and right edges for the contractor mechanisms. The workpiece is indicated by spring with stiffness k_{ss} . Solid and void non-design domains are also depicted. Δ is the output deformation.

FIGURE 3: Optimized gripper mechanisms with two materials (a) Symmetric half optimized gripper mechanism (b) Full optimized gripper mechanism with final pressure field and (c) Deformed profile of full optimized gripper mechanism with final pressure field. Red→ Material 1 (Young's modulus $= 1 \times 10^7 \text{ N m}^{-2}$), Black→Material 2 (Young's modulus $= 1 \times 10^8 \text{ N m}^{-2}$). The output displacement u_{out} is in y direction.

FIGURE 4: Optimized contractor mechanisms with two materials (a) Symmetric half optimized contractor mechanism (b) Full optimized contractor mechanism with final pressure field and (c) Deformed profile of full optimized contractor mechanism with final pressure field. Red→ Material 1 (Young's modulus $= 1 \times 10^7 \text{ N m}^{-2}$), Black→Material 2 (Young's modulus $= 1 \times 10^8 \text{ N m}^{-2}$). The output displacement u_{out} is in y direction.

5.3 Performance comparison

To gain insight into the question of whether combining different materials offers benefits, this section provides a performance comparison study for the gripper mechanism when it is optimized using one and two materials. The design, optimization, and other parameters are the

same as in Sec. 5.1. We consider three cases: CASE I: the gripper is designed using material 1 ($E_1 = 1 \times 10^7 \text{ N m}^{-2}$) and volume fraction 0.30, CASE II: the gripper is designed using material 2 ($E_2 = 1 \times 10^8 \text{ N m}^{-2}$) and volume fraction 0.30 and CASE III: the gripper is designed using material 1 and material 2 with volume fraction 0.15 for each.

(a) Objective convergence history

(b) Convergence plots of volume constraints

FIGURE 5: Convergence plots of the objective and volume constraints for the two-material gripper mechanism.

FIGURE 6: Optimized gripper mechanisms with three materials (a) Symmetric half optimized gripper mechanism (b) Full optimized gripper mechanism with final pressure field and (c) Deformed profile of full optimized gripper mechanism with final pressure field. Yellow→ Material 1 (Young's modulus $=1 \times 10^7 \text{ N m}^{-2}$), red→Material 2 (Young's modulus $=0.51 \times 10^8 \text{ N m}^{-2}$) and black→Material 3 (Young's modulus $=1 \times 10^8 \text{ N m}^{-2}$). The output displacement u_{out} is in y direction.

FIGURE 7: Optimized contractor mechanisms with three materials (a) Symmetric half optimized contractor mechanism (b) Full optimized contractor mechanism with final pressure field and (c) Deformed profile of full optimized contractor mechanism with final pressure field. Red→ Material 1 (Young's modulus $=1 \times 10^7 \text{ N m}^{-2}$), Black→Material 2 (Young's modulus $=1 \times 10^8 \text{ N m}^{-2}$). The output displacement u_{out} is in y direction.

The optimized designs for CASE I, CASE II and CASE III with the final pressure field are depicted in Fig. 8a, Fig. 8b and Fig. 8c, respectively. The optimized topology of CASE I and CASE II are the

same, which should be the case as we consider a linear mechanics setting. The obtained output displacements for CASE I, CASE II and CASE III are -3.4 mm , -2.4 mm and -6.5 mm . It can be noted that the mechanism

FIGURE 8: Optimized results for the gripper mechanisms for different cases. (a) CASE I, (b) CASE II, (c) CASE III. Red \rightarrow Material 1 (Young's modulus $=1 \times 10^7 \text{ N m}^{-2}$), black \rightarrow Material 2 (Young's modulus $=1 \times 10^8 \text{ N m}^{-2}$)

of CASE III, i.e., with two materials, performs clearly better than that of CASE I and CASE II. We expect a similar trend with three or more than three materials. Therefore, the numerical experiment performed here establishes that the use of multiple materials significantly increases the potential performance that can be achieved. In fact, the performance has nearly doubled. It should also be noted that an equal volume constraint was used on both materials, which is an arbitrary choice and which is likely not the optimal ratio. Hence, the true potential of a multi-material design might be even higher.

6 Concluding remarks

This paper presents a density-based topology optimization approach to design pneumatically actuated multi-material compliant mechanisms. The success of the proposed method is demonstrated by creating two- and three-material gripper and contractor mechanisms. The extended SIMP scheme is employed for modeling multiple materials. Output deformation in the robust TO setting with constraints on volume and strain energy is maximized. The upper limit on the strain energy is evaluated at the beginning of the optimization. The given volume constraints on the material are satisfied and remain active at the end of the optimization.

The Darcy law proposed in [26] is extended for modeling pressure loads with many candidate materials in a topology optimization setting. The flow coefficient of an element is determined using its solid and void phases' flow coefficient, irrespective of the candidate material type. A standard finite element formulation converts the distributed pressure field into consistent nodal loads. The load sensitivities arising due to the design-dependent nature of the loads are readily determined and considered within the formulation.

The output deformations of the mechanisms are obtained in the desired directions. We demonstrate via numerical experiments that a mechanism optimized using multiple materials performs significantly better than when optimized for a single individual material. Small-deformation finite element analysis has been applied, i.e., nonlinearities due to geometry and material behavior must be addressed. Considering these nonlinearities for more realistic cases with experimental verification forms the future direction for optimizing such mechanisms.
