Keywords: Logic-based switching Distributed control Dynamic boundary function Unknown control directions

A B S T R A C T

This work studies logic-based distributed switching control for nonlinear agents in power-chained form, where logic-based (switching) control arises from the online estimation of the control directions assumed to be unknown for all agents. Compared to the state-of-the-art logic-based mechanisms, the challenge of power-chained dynamics is that in general asymptotic tracking cannot be obtained, even for a single agent. To address this challenge, a new logic-based mechanism is proposed, which is orchestrated by a dynamic boundary function. The boundary function is decreasing in-between switching instants and monotonically increasing at the switching instants, depending on the jumps of an appropriately designed Lyapunov-like function. To remove chattering (i.e. two or more switching instants occurring consecutively with zero dwell time), a dynamic threshold is proposed, based on selecting the maximum values of the Lyapunov-like function before and after switching. © 2022 The Authors. [\(http://creativecommons.org/licenses/by/4.0/](http://creativecommons.org/licenses/by/4.0/)).

second, dynamics in power-chained form can describe relevant classes of practical systems such as dynamical boiler-turbine units ([Chen & Chen](#page-9-12), [2020\)](#page-9-12), or hydraulic dynamics [\(Manring &](#page-9-13) [Fales,](#page-9-13) [2019\)](#page-9-13). Besides, [Lin and Pongvuthithum](#page-9-9) [\(2003](#page-9-9)), [Lin et al.](#page-9-10) ([2002\)](#page-9-10) and [Qian and Lin](#page-9-11) [\(2002](#page-9-11)) have shown that some classes of under-actuated, weakly coupled mechanical systems with cubic force–deformation relations (nonlinear spring forces) can also be captured by power-chained form. It was shown that, even for a single agent, asymptotic tracking for this class of dynamics is structurally impossible, even locally, because the linearized dynamics contain uncontrollable modes whose eigenvalues are on the right half plane [\(Lin & Pongvuthithum](#page-9-9), [2003](#page-9-9)). In fact, the results in the literature for power-chained dynamics achieve practical or semiglobal ([Lin & Pongvuthithum,](#page-9-9) [2003](#page-9-9); [Lin et al.,](#page-9-10) [2002;](#page-9-10) [Lv, Yu, Cao, & Baldi](#page-9-14), [0000a;](#page-9-14) [Qian & Lin,](#page-9-11) [2002;](#page-9-11) [Shi, Liu,](#page-9-15) [Dong, & Chen](#page-9-15), [2018;](#page-9-15) [Zhao, Shi, Zheng, & Zhang,](#page-9-16) [2016;](#page-9-16) [Zhao,](#page-9-17) [Wang, Zong, & Zheng](#page-9-17), [2017\)](#page-9-17) stability, in place of asymptotic stability. This implies that distributed asymptotic tracking for power-chained dynamics, is also structurally impossible in general. Furthermore, state-of-the-art results [\(Lv et al.,](#page-9-14) [0000a](#page-9-14); [Shi](#page-9-15) [et al.](#page-9-15), [2018](#page-9-15)) for power-chained dynamics rely on the assumption that the agents' control directions (i.e. the signs of the control gain functions) are known *a priori*. When such *a priori* knowledge is not available ([Wang](#page-9-2), [0000a](#page-9-2)), a popular approach to tackle this challenge is continuous parameter adaptation via Nussbaum functions ([Chen](#page-9-18), [2019;](#page-9-18) [Ding & Ye](#page-9-19), [2002](#page-9-19); [Huang, Wang, Wen,](#page-9-20) [& Zhou](#page-9-20), [2018;](#page-9-20) [Lv, Yu, Cao, & Baldi,](#page-9-21) [0000b](#page-9-21); [Nussbaum](#page-9-22), [1983;](#page-9-22)

1. Introduction

Recent years have witnessed a tremendous progress in the field of distributed control of nonlinear multi-agent systems ([Ding,](#page-9-0) [2015;](#page-9-0) [Fan, Yang, Jagannathan, & Sun](#page-9-1), [2019](#page-9-1); [Wang,](#page-9-2) [0000a;](#page-9-2) [Wang, Wen, & Huang,](#page-9-3) [2017](#page-9-3); [Wang, Wen, Huang, & Zhou](#page-9-4), [0000b;](#page-9-4) [Yoo](#page-9-5), [2018\)](#page-9-5). Such results can be categorized according to two large families of nonlinear dynamics: strict-feedback ([Chen, Li,](#page-9-6) [Ren, & Wen](#page-9-6), [2014](#page-9-6); [Chen et al.](#page-9-7), [2017](#page-9-7); [Ding](#page-9-0), [2015;](#page-9-0) [Wang](#page-9-2), [0000a;](#page-9-2) [Wang et al.](#page-9-3), [2017](#page-9-3), [0000b\)](#page-9-4) and pure-feedback [\(Fan et al.](#page-9-1), [2019;](#page-9-1) [Wang & Song,](#page-9-8) [2017](#page-9-8); [Yoo,](#page-9-5) [2018](#page-9-5)) dynamics. At the same time, another family of dynamics, namely *power-chained form*, has been attracting great attention. The reason is twofold: first, powerchained dynamics are a generalization of strict-feedback and pure-feedback dynamics since they include more general integrators (with positive odd-integer-powers) ([Lin & Pongvuthithum,](#page-9-9) [2003;](#page-9-9) [Lin, Pongvuthithum, & Qian,](#page-9-10) [2002](#page-9-10); [Qian & Lin,](#page-9-11) [2002\)](#page-9-11);

[Wang](#page-9-2), [0000a](#page-9-2); [Ye & Jiang](#page-9-23), [1998](#page-9-23)), which has been used also for distributed control of strict-feedback or pure-feedback dynamics ([Chen et al.,](#page-9-6) [2014,](#page-9-6) [2017](#page-9-7); [Ding](#page-9-0), [2015](#page-9-0); [Fan et al.](#page-9-1), [2019](#page-9-1); [Wang,](#page-9-2) [0000a](#page-9-2)). At the same time, because it is well-recognized that Nussbaum-based methods require additional complexity in the control design and continuous parameter adaptation may lead to large learning transients, several researchers have been engaged in the problem of overcoming continuous parameter adaptation by means of logic-based control [\(Hespanha, Liberzon, &](#page-9-24) [Morse,](#page-9-24) [2003;](#page-9-24) [Liberzon](#page-9-25), [2003\)](#page-9-25). Notable settings where logic-based adaptation was employed include overcoming conventional continuous tuning of control parameters [\(Angeli & Mosca,](#page-9-26) [2004;](#page-9-26) [Ye](#page-9-27), [2003](#page-9-27), [2005](#page-9-28)) and overcoming the conventional Nussbaum approach for strict-feedback dynamics ([Huang & Yu](#page-9-29), [2018;](#page-9-29) [Wu,](#page-9-30) [Chen, & Li,](#page-9-30) [2016\)](#page-9-30).

It is crucial to notice that the state-of-the-art logic-based mechanisms in [Huang and Yu](#page-9-29) ([2018](#page-9-29)) and [Wu et al.](#page-9-30) ([2016](#page-9-30)) for strict-feedback systems rely on monitor functions that monitor whether asymptotic tracking can be achieved (resulting in bounded energy of the tracking error) [\(Huang & Yu](#page-9-29), [2018](#page-9-29)) or whether finite-time stabilization can be achieved (i.e. the tracking error converges to zero in finite time) [\(Wu et al.,](#page-9-30) [2016](#page-9-30)). Unfortunately, the same mechanism and monitor functions cannot be adopted for agents in power-chained form due to the aforementioned structural difficulty in achieving asymptotic tracking, see also [Qian and Lin](#page-9-11) [\(2002](#page-9-11), Examples 2.1 and 2.2). Therefore, a different logic-based mechanism must be sought for distributed control of power-chained dynamics. This motivates the research question in this work: *is it possible to design a new logic-based mechanism for multi-agent systems in power-chained form with multiple unknown control directions even when asymptotic tracking cannot be structurally obtained?*

This paper provides a positive answer to this question with the following contributions:

(i) To overcome the challenge that the exact value of the Lyapunov function is unavailable for logic-based adaptation, we propose a new Lyapunov-like function (cf. the discussion in [Re](#page-5-0)[mark](#page-5-0) [3](#page-5-0)).

(ii) We formally exclude any chattering phenomena by proposing a new dynamic threshold condition at the switching instants of the logic-based adaptation. It is worth noticing that state-ofthe-art switching mechanisms cannot formally exclude chattering (cf. the discussion in [Remark](#page-5-1) [4](#page-5-1));

(iii) To overcome the difficulty that no asymptotic tracking can be achieved for the power-chained form, we propose a new dynamic boundary function, which is decreasing in-between switching instants and possibly increasing at the switching instants of the logic-based adaptation (cf. [Fig.](#page-2-0) [1](#page-2-0) and the discussion in [Remark](#page-6-0) [5\)](#page-6-0);

Notations: The sets $\mathbb R$ and $\mathbb R^n$ stand for the set of real numbers and the *n*-dimensional Euclidean space, respectively; N_{odd} denotes the set of positive odd integers; ∥ · ∥ refers to either the Euclidean vector norm or the induced matrix 2-norm. Vectors are denoted in bold script, such as $\overline{\chi}_{i,m}$ $W_{i,m}$, $\varphi_{i,m}$, $Z_{i,m}$, $d_{i,\sigma}$, and $h_i(\cdot)$. For compactness and whenever unambiguous, some variable dependencies might be dropped throughout this paper, e.g. *ι*, $\psi_{i,m}$, $s_{i,m}$, $r_{i,m}$ can be used to represent $\iota(x_1, x_2)$, $\psi_{i,m}(\overline{\chi}_{i,m})$, $s_{i,m}(\vartheta_{i,m}, \alpha_{i,m-1}), r_{i,m}(\vartheta_{i,m}, \alpha_{i,m-1}),$ respectively.

2. Problem formulation and preliminaries

Let us first give some preliminaries on graph theory. The communication topology among agents is described by a directed graph $\mathscr{G} \triangleq (\mathscr{V}, \mathscr{E})$, with $\mathscr{V} \triangleq \{0, 1, \ldots, N\}$ the set of nodes (agents) and with $\mathscr{E} \subseteq \mathscr{V} \times \mathscr{V}$ the set of directed edges between two distinct agents. A directed edge $(j, i) \in \mathcal{E}$ represents that agent

Fig. 1. The sketch of the proposed switching mechanism.

i can obtain information from agent *j*. The neighbor set of agent *i* is denoted by $\mathcal{N}_i = \{j | (j, i) \in \mathcal{E}\}\$. Because agent 0 plays a special role (leader), let us consider the subgraph defined by $\overline{\mathscr{G}} \triangleq (\overline{\mathscr{V}}, \overline{\mathscr{E}})$ with $\overline{\psi} \triangleq \{1, 2, \ldots, N\}$ the set of follower agents and $\overline{\mathscr{E}}$ defined accordingly. For this subgraph, let us define the adjacency matrix $\overline{A} = [a_{ij}] \in \mathbb{R}^{N \times N}$ as follows: if $(j, i) \in \overline{\mathscr{E}}$, then $a_{ij} = 1$, otherwise a_{ij} = 0. The Laplacian matrix $\mathscr L$ associated with $\mathscr G$ is defined as $\mathscr{L} = \begin{bmatrix} 0 & \mathbf{0}_{1 \times N} \\ h & \overline{\mathscr{L}} \end{bmatrix}$ $-b$ $\overline{\mathscr{L}} + \mathscr{B}$ $\left[\begin{array}{rcl} \text{with}\ \mathscr{B}\ =\ \text{diag}[b_1,\ldots,b_N],\ \text{where}\end{array}\right]$ $b_i = 1$ if the leader $0 \in \mathcal{N}_i$, and $b_i = 0$ otherwise. Moreover, $b = [b_1, \ldots, b_N]^T$ and $\overline{\mathscr{L}} = \overline{\mathscr{D}} - \overline{\mathscr{A}}$ is the Laplacian matrix related

to $\overline{\mathscr{D}}$ with $\overline{\mathscr{D}} = \text{diag}[d_1, \dots, d_N]$, where $d_i = \sum_{j \in \mathscr{N}_i} a_{ij}$. Consider a multi-agent system whose agents have the follow-

ing nonlinear dynamics

$$
\begin{cases}\n\dot{\chi}_{i,m} = \phi_{i,m}(\overline{\chi}_{i,m}) + \psi_{i,m}(\overline{\chi}_{i,m}) \chi_{i,m+1}^{p_{i,m}},\\ \n\dot{\chi}_{i,n_i} = \phi_{i,n_i}(\overline{\chi}_{i,n_i}) + \psi_{i,n_i}(\overline{\chi}_{i,n_i}) u_i^{p_{i,n_i}},\\ \ny_i = \chi_{i,1},\n\end{cases} \tag{1}
$$

for $i = 1, \ldots, N$, $m = 1, \ldots, n_i - 1$, where n_i is the dimension of system state $\overline{\chi}_{i,n_i} = [\chi_{i,1}, \ldots, \chi_{i,n_i}]^T \in \mathbb{R}^{n_i}$ and $\overline{\chi}_{i,m}$ $[\chi_{i,1}, \ldots, \chi_{i,m}]^T \in \mathbb{R}^m$. In [\(1\)](#page-2-1), $p_{i,m} \in \mathbb{N}_{odd}$ are positive odd powers, and $u_i \in \mathbb{R}$ is the agent control input to be designed. The functions $\phi_{i,m}(\cdot)$ and $\psi_{i,m}(\cdot)$ are unknown locally Lipschitz continuous nonlinearities. The following assumptions are considered.

Assumption 1. For each follower *i*, the signs of $\psi_{i,m}(\cdot)$, called the *control directions*, are unknown and there exist known positive constants $\psi_{i,m}$ and $\underline{\psi}_{i,m}$ such that

$$
\underline{\psi}_{i,m} \le |\psi_{i,m}(\cdot)| \le \overline{\psi}_{i,m} \tag{2}
$$

for $i = 1, ..., N, m = 1, ..., n_i$.

Assumption 2 (*[Wang et al.,](#page-9-3) [2017](#page-9-3)*)**.** The leader agent 0 is represented by a leader output signal *y*^r , which is continuous, bounded and with bounded derivative; y_r is available only to the subset of follower agents *i* such that agent $0 \in \mathcal{N}_i$, i.e. to those agents directly connected to the leader according to directed graph \mathscr{G} .

Assumption 3 (*[Wang et al.](#page-9-3), [2017](#page-9-3)*). The directed graph $\mathscr G$ contains at least one directed spanning tree with the leader as the root. This implies that $\overline{\mathscr{L}} + \mathscr{B}$ is nonsingular.

Remark 1. The bounds in [\(2](#page-2-2)) are standardly assumed to ensure controllability of the system ([Qian & Lin](#page-9-11), [2002;](#page-9-11) [Shi et al.](#page-9-15), [2018;](#page-9-15) [Zhao et al.](#page-9-16), [2016](#page-9-16), [2017\)](#page-9-17); [Assumptions](#page-2-3) [2–](#page-2-3)[3](#page-2-4) are also standard in literature. The peculiar characteristic (and challenge) of (1) (1) as compared to other multi-agent system models proposed in the literature, are the unknown multiple control directions in [Assumption](#page-2-5) [1.](#page-2-5) Although some works have addressed multi-agent systems with unknown control directions [\(Chen et al.,](#page-9-6) [2014,](#page-9-6) [2017;](#page-9-7) [Ding,](#page-9-0) [2015](#page-9-0); [Fan et al.](#page-9-1), [2019](#page-9-1); [Wang,](#page-9-2) [0000a](#page-9-2)), the dynamics therein are in the form of strict-feedback systems.

Define the consensus tracking error for the *i*th follower as

$$
\xi_{i,1} = \sum_{j \in \mathcal{N}_i} a_{ij} (y_i - y_j) + b_i (y_i - y_r), \tag{3}
$$

for $i = 1, \ldots, N$. After collecting $\xi_1 = [\xi_{1,1}, \ldots, \xi_{N,1}]^T \in \mathbb{R}^N$, one has $\xi_1 = (\overline{\mathscr{L}} + \mathscr{B})\omega$, where $\omega = \overline{\mathbf{y}} - \overline{\mathbf{y}}_{\text{r}}$ with $\overline{\mathbf{y}} = [y_1, \dots, y_N]^T$ and $\overline{\mathbf{y}}_r = [y_r, \ldots, y_r]^T$. Due to the nonsingularity of $\overline{\mathscr{L}} + \mathscr{B}$, it holds that $\|\omega\| \leq \frac{\|\xi_1\|}{\sigma_{\min}(\mathcal{L}+\mathcal{B})}$, where $\sigma_{\min}(\mathcal{L}+\mathcal{B})$ is the minimum singular value of $\overline{\mathscr{L}} + \mathscr{B}$. We impose a prescribed performance [\(Bechlioulis & Rovithakis](#page-9-31), [2014](#page-9-31)) on the consensus tracking error $\xi_{i,1}$ as $\underline{\xi}_{i,1}(t) \leq \xi_{i,1}(t) \leq \overline{\xi}_{i,1}(t)$ for $t \geq 0$, where $\bar{\xi}_{i,1}(t) = (\bar{\rho}_{i,1} - \rho_{i,\infty}) \exp(-\bar{l}_{i,1}t) + \rho_{i,\infty}$ and $\underline{\xi}_{i,1}(t) =$ $(\underline{\rho}_{i,1} + \rho_{i,\infty})$ exp $(-\underline{l}_{i,1}t) - \rho_{i,\infty}$ are the so-called performance functions [\(Bechlioulis & Rovithakis](#page-9-31), [2014\)](#page-9-31), where $\bar{l}_{i,1} > 0$ and $l_{i,1} > 0$ denote the minimum admissible convergence rates, $\rho_{\text{i},\infty}>0$ is the maximum allowable tracking error at steady state, $\overline{\rho}_{i,1} > \rho_{i,\infty} > 0$ and $\rho_{i,1} < -\rho_{i,\infty} < 0$ respectively represent the maximum and minimum bounds for $\xi_{i,1}(0)$. The following transformed consensus tracking error is then used for feedback:

$$
\vartheta_{i,1}(t) = \ln\left(\frac{\xi_{i,1}(t) - \underline{\xi}_{i,1}(t)}{\overline{\xi}_{i,1}(t) - \xi_{i,1}(t)}\right).
$$
\n(4)

Note that $\vartheta_{i,1}$ is monotonically increasing w.r.t. $\xi_{i,1}$ and that ([4\)](#page-3-0) implies that the consensus tracking error ξ*i*,¹ is within its imposed bounds provided $\vartheta_{i,1}$ is bounded [\(Bechlioulis & Rovithakis](#page-9-31), [2014\)](#page-9-31).

Consensus tracking problem: Under dynamics ([1\)](#page-2-1) and [As](#page-2-5)[sumptions](#page-2-5) $1-3$ $1-3$, the goal is to design u_i such that all closed-loop signals are semi-globally ultimately uniformly bounded, and the output of each follower agent *i* can follow the leader agent's signal *y*r in spite of completely multiple unknown control directions.

Practical tracking ([Qian & Lin,](#page-9-11) [2002,](#page-9-11) eq. (2.10)) (i.e. the tracking error converges to a residual set) will be sought, due to the fact that asymptotic tracking cannot be realized in general for dynamics [\(1\)](#page-2-1) [\(Qian & Lin](#page-9-11), [2002\)](#page-9-11). The following lemmas are instrumental in solving the practical tracking problem.

Lemma 1 (*[Lin & Pongvuthithum,](#page-9-9) [2003](#page-9-9)*). *For any* $x_1, x_2 \in \mathbb{R}$ *, given positive integers* r_1 , r_2 *and any real-valued function* $\iota(\cdot, \cdot) > 0$, *it holds that*

$$
|x_1|^{r_1}|x_2|^{r_2} \le \frac{r_2}{r_1+r_2} \iota(x_1, x_2)^{-\frac{r_1}{r_2}} |x_2|^{r_1+r_2} + \frac{r_1}{r_1+r_2} \iota(x_1, x_2) |x_1|^{r_1+r_2}.
$$
 (5)

Lemma 2 (*[Lv et al.](#page-9-14), [0000a](#page-9-14)*). For any $x_1, x_2 \in \mathbb{R}$, and positive odd *integer* $p \in \mathbb{N}_{\text{odd}}$ *, it holds that*

$$
(x_1 + x_2)^p = r(x_1, x_2)x_1^p + s(x_1, x_2)x_2^p \tag{6}
$$

where $r(x_1, x_2) \in [r, \bar{r}]$ *with* $r = 1 - \delta$ *and* $\bar{r} = 1 + \delta$ *, and* $\delta = \sum_{k=1}^p \frac{p!}{k!(p-k)!} \frac{p-k}{p} l^{\frac{p}{p-k}}$ is a constant taking value in (0, 1) for *some appropriately small constant l, and where* $|s(x_1, x_2)| \leq \overline{s}(\delta)$ *with* $\overline{s(\delta)} = \sum_{k=1}^p \frac{p!}{k!(p-k)!} \frac{k}{p} l^{-\frac{p}{k}}$ a positive constant for a given l.

3. Adaptive switching consensus protocol

The control design solving the consensus tracking problem comprises a *continuous* input (i.e. acting in-between two consecutive switching instants) and a *switching* mechanism (acting at the switching instants) to tune online some parameters of the continuous input. In this section, we focus on the continuous input, the design of which is well-established in literature under the assumption that the control directions are known ([Shi et al.,](#page-9-15) [2018\)](#page-9-15).

After defining $\vartheta_{i,1}$ as in ([4\)](#page-3-0), and state errors

$$
\vartheta_{i,m} = \chi_{i,m} - \alpha_{i,m-1}, \quad m = 2, \ldots, n_i,
$$
\n
$$
(7)
$$

the continuous control input comprises the so-called virtual laws $\alpha_{i,m}$ and the actual control u_i , designed as

$$
\alpha_{i,1} = -h_{i,1} \mathfrak{S}_{i,1}^{\frac{1}{p_{i,1}}} \left(k_{i,1} + \epsilon_{i,1}^{\bar{p}_{i,1}} \widehat{\Theta}_{i,1} \Gamma_{i,1}^{\bar{p}_{i,1}} + \varrho_{i,1}^{\bar{p}_{i,1}} \right)^{\frac{1}{p_{i,1}}} \tag{8}
$$

$$
\mathfrak{S}_{i,1} = \vartheta_{i,1}^{p_{i,1}} \left[\ell_{i,1} \underline{\psi}_{i,1} (d_i + b_i) (1 - \delta_{i,1}) \right]^{-1},
$$
\n
$$
\alpha_{i,m} = -h_{i,m} \mathfrak{S}_{i,m}^{\frac{1}{p_{i,m}}} \left(k_{i,m} + \epsilon_{i,m}^{\overline{p}_{i,m}} \widehat{\Theta}_{i,m} \Gamma_{i,m}^{\overline{p}_{i,m}} + \varrho_{i,m}^{\overline{p}_{i,m}} \right)^{\frac{1}{p_{i,m}}} \tag{9}
$$

$$
\mathfrak{S}_{i,m} = \vartheta_{i,m}^{p_{i,m}} \left[\underline{\psi}_{i,m} (1 - \delta_{i,m}) \right]^{-1}, (m = 1, \dots, n_i)
$$

$$
u_i = \alpha_{i,n_i}, \delta_{i,n_i} = 0,
$$

\n
$$
\widehat{\Theta}_{i,m} = \gamma_{i,m} \bigg[\epsilon_{i,m}^{\overline{p}_{i,m}} \vartheta_{i,m}^{p_i+3} \Gamma_{i,m}^{\overline{p}_{i,m}} - \beta_{i,m} \widehat{\Theta}_{i,m} \bigg].
$$
\n(11)

with $\bar{p}_{i,m} = \frac{p_i+3}{p_i-p_{i,m}+3}, \underline{p}_{i,m} = \frac{p_i+3}{p_{i,m}}$ p_{i+m} , $p_i = \max_{m=1,...,n_i} \{p_{i,m}\}$, and where $0 < \delta_{i,m} < 1$, $\varrho_{i,m} > 0$, $\epsilon_{i,m} > 0$, $\gamma_{i,m} > 0$ and $\beta_{i,m} > 0$ $0, (m = 1, \ldots, n_i)$ are design parameters. In ([11](#page-3-1)), $\widehat{\Theta}_{i,m}$ is the estimate of $\widehat{\Theta}$ and $\widehat{\mathbf{F}}$ and estimate of $\Theta_{i,m} = ||\mathbf{W}_{i,m}^*||^{\overline{p}_{i,m}}$ and $\Gamma_{i,m} = ||\boldsymbol{\varphi}_{i,m}||$, which comes from appropriately designed function approximators (as detailed later on). Notice that the control design $(8)-(11)$ $(8)-(11)$ $(8)-(11)$ $(8)-(11)$ is not complete, since the terms $k_{i,m}$ and $h_{i,m}$ are to be designed: these terms are necessary to tackle the multiple unknown control directions, and their design will be addressed in Section [4](#page-4-0) via a switching mechanism. The rationale for the design (8) (8) – (11) is given in the following steps.

Step *i*, 1 (*i* = 1, ..., *N*): The time derivative of ϑ _{*i*,1} along [\(1](#page-2-1)), ([3\)](#page-3-3), and (4) (4) (4) is

$$
\dot{\vartheta}_{i,1} = l_{i,1}\dot{\xi}_{i,1} + H_{i,1} = l_{i,1}(d_i + b_i)\psi_{i,1}\chi_{i,2}^{p_{i,1}} + E_{i,1},
$$
\n(12)

where $l_{i,1} = \partial \vartheta_{i,1}/\partial \xi_{i,1} > 0$, $H_{i,1} = (\partial \vartheta_{i,1}/\partial \overline{\xi}_{i,1})\dot{\overline{\xi}}_{i,1} +$ $(\partial \vartheta_{i,1}/\partial \underline{\xi}_{i,1})\underline{\xi}_{i,1}$, and $E_{i,1} = l_{i,1}(d_i + b_i)\phi_{i,1} - l_{i,1}\sum_{j \in \mathcal{N}_i} a_{ij} \times (\phi_{i,1} + \phi_{i,1})$ $\psi_{i,1}\chi_{i,2}^{p_{i,1}}$) – $b_i\dot{y}_r$ + $H_{i,1}$. Along the same veins as [Yoo](#page-9-32) [\(2013b](#page-9-32)), there exist some optimal weights $W_{i,1}^*$, and a linear-in-the-parameter approximator $W^*_{i,1}\varphi_{i,1}(\vec{Z}_{i,1})$ for $\overline{|E_{i,1}|}$ such that

$$
\vartheta_{i,1}^{p_i-p_{i,1}+3} E_{i,1} \leq \left| \vartheta_{i,1}^{p_i-p_{i,1}+3} \right| \left[\boldsymbol{W}_{i,1}^* \boldsymbol{\varphi}_{i,1}(\boldsymbol{Z}_{i,1}) + \varepsilon_{i,1}(\boldsymbol{Z}_{i,1}) \right] \n\leq \vartheta_{i,1}^{p_i+3} \left(\varrho_{i,1}^{\overline{p}_{i,1}} + \epsilon_{i,1}^{\overline{p}_{i,1}} \Theta_{i,1} \Gamma_{i,1}^{\overline{p}_{i,1}} \right) + \mu_{i,1},
$$

where the last inequality uses [Lemma](#page-3-4) [1.](#page-3-4) Furthermore, $\mu_{i,1}$ = $\epsilon_{i,1}^{-p_{i,1}} + \varrho_{i,1}^{-p_{i,1}} \epsilon_{i,1}^{p_{i,1}}$ with $\epsilon_{i,1} > 0$ and $\varrho_{i,1} > 0$ being design constants, $\varepsilon_{i,1}(Z_{i,1})$ is the approximation error satisfying $\left|\varepsilon_{i,1}(Z_{i,1})\right| \le$ $\overline{\varepsilon}_{i,1}$ on a compact set $\Omega_{i,1}$, $\mathbf{Z}_{i,1} = \begin{bmatrix} \chi_{i,1}, \chi_{j,1,j \in \mathcal{N}_i}, \chi_{j,2,j \in \mathcal{N}_i}, b_i y_r, \end{bmatrix}$ $b_i \dot{y}_r$ $\big]^{T} \in \Omega_{i,1}$, and $\overline{\varepsilon}_{i,1} > 0$ a constant.

Remark 2. The continuous function $|E_{i,1}|$ in ([12\)](#page-3-5) embeds the effect of graph connectivity, since $|E_{i,1}|$ depends on the connectivity matrix a_{ij} and b_i . Note that, because the activation function $\varphi_{i,1}(\cdot)$ of the linear-in-the-parameter approximation relies on the neigh-boring states, standard universal approximation results ([Ferik,](#page-9-33) [Qureshi, & Lewis,](#page-9-33) [2014\)](#page-9-33) of linear-in-the-parameter approximation still hold. Similar approximation ideas also can be found in [Ferik et al.](#page-9-33) [\(2014](#page-9-33)), [Yoo](#page-9-34) ([2013a](#page-9-34)) and [Yoo](#page-9-5) ([2018](#page-9-5)). Simulation results in this paper also validate this point (cf. [Figs.](#page-7-0) [7](#page-7-0) and [8\)](#page-8-0).

Consider the Lyapunov function candidate

$$
V_{i,1} = \frac{\vartheta_{i,1}^{p_i - p_{i,1} + 4}}{p_i - p_{i,1} + 4} + \frac{1}{2\gamma_{i,1}} \widetilde{\Theta}_{i,1}^2
$$
\n(13)

where $\widetilde{\Theta}_{i,1} = \Theta_{i,1} - \widehat{\Theta}_{i,1}$ $\widetilde{\Theta}_{i,1} = \Theta_{i,1} - \widehat{\Theta}_{i,1}$ $\widetilde{\Theta}_{i,1} = \Theta_{i,1} - \widehat{\Theta}_{i,1}$. According to [Lemmas](#page-3-4) 1 and [2,](#page-3-6) it holds that

$$
\vartheta_{i,1}^{p_i-p_{i,1}+3} \chi_{i,2}^{p_{i,1}} = s_{i,1} \vartheta_{i,1}^{p_i-p_{i,1}+3} \vartheta_{i,2}^{p_{i,1}} + r_{i,1} \vartheta_{i,1}^{p_i-p_{i,1}+3} \alpha_{i,1}^{p_{i,1}}
$$

< $|s_{i,1}| (\vartheta_{i,1}^{p_i+3} + \vartheta_{i,2}^{p_i+3}) + r_{i,1} \vartheta_{i,1}^{p_i-p_{i,1}+3} \alpha_{i,1}^{p_{i,1}}.$ (14)

Then, it follows from (12) (12) , (13) (13) (13) , and (14) that the derivative of $V_{i,1}$ with respect to time is

$$
\dot{V}_{i,1} < l_{i,1}(d_i + b_i) \vartheta_{i,1}^{p_i - p_{i,1} + 3} \alpha_{i,1}^{p_{i,1}} h_{i,1} r_{i,1} |\psi_{i,1}| - \frac{\widetilde{\Theta}_{i,1} \widehat{\Theta}_{i,1}}{\gamma_{i,1}} \\
+ \vartheta_{i,1}^{p_i + 3} \left(\varrho_{i,1}^{\overline{p}_{i,1}} + \epsilon_{i,1}^{\overline{p}_{i,1}} \Theta_{i,1} r_{i,1}^{\overline{p}_{i,1}} \right) + \Delta_{i,1} + \mu_{i,1} \\
+ \varpi_{i,1} \left(\vartheta_{i,1}^{p_i + 3} + \vartheta_{i,2}^{p_i + 3} \right), \tag{15}
$$

where $\Delta_{i,1} = l_{i,1}(d_i + b_i)r_{i,1}\vartheta_{i,1}^{p_i-p_{i,1}+3}\alpha_{i,1}^{p_{i,1}}(\text{sign}(\psi_{i,1}) - h_{i,1})|\psi_{i,1}|$ $\overline{\omega}_{i,1}$ = $(d_i + b_i)l_{i,1}\overline{\psi}_{i,1}\overline{s}_{i,1}$, and we used the fact that $\psi_{i,1}$ = $sign(\psi_{i,1})|\psi_{i,1}|$. Substituting the virtual control $\alpha_{i,1}$ [\(8\)](#page-3-2) into [\(15\)](#page-4-3) gives

$$
\dot{V}_{i,1} < - (k_{i,1} - \varpi_{i,1}) \vartheta_{i,1}^{p_i+3} + \vartheta_{i,1}^{p_i+3} \epsilon_{i,1}^{\bar{p}_{i,1}} \widetilde{\Theta}_{i,1} \Gamma_{i,1}^{\bar{p}_{i,1}} \n- \frac{\widetilde{\Theta}_{i,1} \widehat{\Theta}_{i,1}}{\gamma_{i,1}} + \varpi_{i,1} \vartheta_{i,2}^{p_i+3} + \Delta_{i,1} + \mu_{i,1}.
$$
\n(16)

Substituting the adaptive law $\widehat{\Theta}_{i,1}$ ([11\)](#page-3-1) into ([16](#page-4-4)) yields

$$
\dot{V}_{i,1} < -c_{i,1} \vartheta_{i,1}^{p_i+3} + \varpi_{i,1} \vartheta_{i,2}^{p_i+3} - \beta_{i,1} \widetilde{\Theta}_{i,1} \widehat{\Theta}_{i,1} + \Delta_{i,1} + \mu_{i,1},
$$
\nwhere $c_{i,1} = k_{i,1} - \varpi_{i,1}$.

\n**Sten** *i* m (*i* = 1, 1, 1) *N* $m = 2$, 1): It follows from:

Step *i*, *m* (*i* = 1, . . . , *N*, *m* = 2, . . . , *n_i* − [1\)](#page-2-1): It follows from (1), ([7](#page-3-7)), and [\(9](#page-3-8)) that the derivative of $\vartheta_{i,m}$ is

$$
\dot{\vartheta}_{i,m} = \psi_{i,m} \chi_{i,m+1}^{p_{i,m}} + E_{i,m}, \qquad (17)
$$

where $E_{i,m} = \phi_{i,m} - \sum_{q=1}^{m-1} \frac{\partial \alpha_{i,m-1}}{\partial \chi_{i,q}}$ $\frac{\partial \alpha_{i,m-1}}{\partial x_{i,q}}(\phi_{i,q} + \psi_{i,q} \chi_{i,q+1}^{p_{i,q}}) - \frac{\partial \alpha_{i,m-1}}{\partial y_r} \dot{y}_r \sum_{q=1}^{m-1} \frac{\partial \alpha_{i,m-1}}{\partial \widehat{\Theta}_{i,q}}$ $\frac{\alpha_{i,m-1}}{\partial \widehat{\Theta}_{i,q}} \widehat{\Theta}_{i,q} - \sum_{j \in \mathcal{N}_i} a_{ij} \frac{\frac{\partial \alpha_{i,m-1}}{\partial \chi_{j,1}}}{\frac{\partial \chi_{j,1}}{\partial \chi_{j,1}}}$ $\frac{\alpha_{i,m-1}}{\alpha_{\mathcal{X}_{j,1}}}(\phi_{j,1}+\psi_{j,2}\chi_{j,2}^{p_{j,1}}).$ Referring to Step *i*, 1, there exist some optimal weights $W_{i,m}^*$, and a linear-inthe-parameter approximator $\bm{W}_{i,m}^* \bm{\varphi}_{i,m}(\bm{Z}_{i,m})$ for $|E_{i,m}|$ such that

$$
\sigma_{i,m}^{p_i-p_{i,m}+3} E_{i,m} \n\leq |\sigma_{i,m}^{p_i-p_{i,m}+3}| [\mathbf{W}_{i,m}^* \boldsymbol{\varphi}_{i,m}(\mathbf{Z}_{i,m}) + \varepsilon_{i,m}(\mathbf{Z}_{i,m})] \n\leq \sigma_{i,m}^{p_i+3} (\rho_{i,m}^{\bar{p}_{i,m}} + \epsilon_{i,m}^{\bar{p}_{i,m}} \boldsymbol{\varphi}_{i,m} \boldsymbol{\Gamma}_{i,m}^{\bar{p}_{i,m}}) + \mu_{i,m},
$$

where $\mu_{i,m} = \epsilon_{i,m}^{-p_{i,m}} + \varrho_{i,m}^{-p_{i,m}} \overline{\epsilon}_{i,m}^{p_{i,m}}$ with $\epsilon_{i,m} > 0$ and $\varrho_{i,m} > 0$ 0 design constants, $\varepsilon_{i,m}(\boldsymbol{Z}_{i,m})$ is the approximation error satisfying $\left[\varepsilon_{i,m}(Z_{i,m})\right] \leq \overline{\varepsilon}_{i,m}$ on a compact set $\Omega_{i,m}$, with $Z_{i,m} = \left[\overline{\chi}_{i,m}, \overline{\chi}_{j,m}, \frac{\partial \alpha_{i,m-1}}{\partial \chi_{i,1}}, \frac{\partial \alpha_{i,m-1}}{\partial \chi_{i,1}}, \frac{\partial \alpha_{i,m-1}}{\partial \chi_{i,m-1}}, \frac{\partial \alpha_{i,m-1}}{\partial \hat{\theta}_{i,1}}, \dots, \frac{\partial \alpha_{i,m-1}}{\partial \hat{\theta}_{i,m-1}}, \widehat{\Theta}_{i$ $\frac{\alpha_{i,m-1}}{\alpha_{\chi_{j,1}}}$, $\frac{\partial \alpha_{i,m-1}}{\alpha_{\chi_{i,1}}}$ $\frac{\partial \alpha_{i,m-1}}{\partial \chi_{i,1}}, \ldots, \frac{\partial \alpha_{i,m-1}}{\partial \chi_{i,m-1}}$ $\frac{\partial \alpha_{i,m-1}}{\partial \chi_{i,m-1}}, \frac{\partial \alpha_{i,m-1}}{\partial \widehat{\Theta}_{i,1}}$ $\frac{\alpha_{i,m-1}}{\partial \widehat{\Theta}_{i,1}}, \ldots, \frac{\partial \alpha_{i,m-1}}{\partial \widehat{\Theta}_{i,m-1}}$ $\frac{\partial a_{i,m-1}}{\partial \widehat{\Theta}_{i,m-1}}, \widehat{\Theta}_{i,1},$ \ldots , $\widehat{\Theta}_{i,m-1}$, $\frac{\partial \alpha_{i,m-1}}{\partial y_r}$, $b_i y_r$] $^T_{j \in \mathcal{N}_i}$ ∈ $\Omega_{i,m}$ and $\overline{\varepsilon}_{i,m} > 0$ a constant.

Consider the Lyapunov function candidate

$$
V_{i,m} = V_{i,m-1} + \frac{\vartheta_{i,m}^{p_i - p_{i,m} + 4}}{p_i - p_{i,m} + 4} + \frac{1}{2\gamma_{i,m}} \widetilde{\Theta}_{i,m}^2,
$$
\n(18)

where $\widetilde{\Theta}_{i,m} = \Theta_{i,m} - \widehat{\Theta}_{i,m}$. Following similar derivations as in Step *i*, 1, the derivative of $V_{i,m}$ with respect to time is

$$
\dot{V}_{i,m} < -\sum_{q=1}^{m} c_{i,q} \vartheta_{i,q}^{p_i+3} + \varpi_{i,m} \vartheta_{i,m+1}^{p_i+3} + \sum_{q=1}^{m} \varDelta_{i,q}
$$

+
$$
\sum_{q=1}^{m} \left(\frac{\beta_{i,q}}{2} \left(\Theta_{i,q}^{2} - \widetilde{\Theta}_{i,q}^{2} \right) + \mu_{i,q} \right),
$$
 (19)

where $c_{i,m} = k_{i,m} - \varpi_{i,m} - \varpi_{i,m-1}, \varpi_{i,m} = \overline{\psi}_{i,m} \overline{s}_{i,m}$, and $\Delta_{i,m} =$ $\vartheta_{i,m}^{p_i-p_{i,m}+3} \alpha_{i,m}^{p_{i,m}}(\text{sign}(\psi_{i,m})-h_{i,m})r_{i,m}|\psi_{i,m}|, (m=2,\ldots,n_i-1).$ **Step** *i*, n_i ($i = 1, ..., N$): For the last step, consider the Lyapunov function candidate

$$
V_{i,n_i} = V_{i,n_i-1} + \frac{\vartheta_{i,n_i}^{p_i-p_{i,n_i}+4}}{p_i-p_{i,n_i}+4} + \frac{1}{2\gamma_{i,n_i}} \widetilde{\Theta}_{i,n_i}^2,
$$
 (20)

where $\hat{\Theta}_{i,n_i} = \Theta_{i,n_i} - \hat{\Theta}_{i,n_i}$. Along similar lines as the previous stops it is possible to conclude that steps, it is possible to conclude that

$$
\dot{V}_{i,n_i} < -\sum_{q=1}^{n_i} c_{i,q} \vartheta_{i,q}^{p_i+3} + \sum_{q=1}^{n_i} \left(\frac{\beta_{i,q}}{2} \left(\Theta_{i,q}^2 - \widetilde{\Theta}_{i,q}^2 \right) \right) + \sum_{q=1}^{n_i} \mu_{i,q} + \sum_{q=1}^{n_i} \Delta_{i,q},\tag{21}
$$

with $c_{i,n_i} = k_{i,n_i} - \overline{\omega}_{i,n_i-1}$ and $\Delta_{i,n_i} = \vartheta_{i,n_i}^{p_i-p_{i,n_i}+3}$ $\frac{p_i - p_{i,n_i} + 3}{u_i} u_i^{p_{i,n_i}} \times (\text{sign}(\psi_{i,n_i})$ h_{i,n_i})| ψ_{i,n_i} |. For any constant $\eta_i > 0$, in light of [Lemma](#page-3-4) [1](#page-3-4), we have *pi*,*g*−

$$
\eta_i + \vartheta_{i,q}^{p_i+3} \ge \eta_i^{\frac{m_i+3}{p_i+3}} \vartheta_{i,q}^{p_i-p_{i,q}+4}.
$$

Thus, (21) can be upper bounded as

$$
\dot{V}_{i,n_i} < -\varsigma_i V_{i,n_i} + \varepsilon_i + \sum_{q=1}^{n_i} \Delta_{i,q},\tag{22}
$$

where $\zeta_i = \min\{\gamma_{i,q}\beta_{i,q}, (p_i-p_{i,q}+4)c_{i,q}\eta\}$ $\frac{p_{i,q}-1}{p_i+3}$, *i* = 1, . . . , *N*, *q* = $\{1, \ldots, n_i\}, \ \mathcal{Z}_i = \sum_{q=1}^{n_i} (c_{i,q} \eta_i + \mu_{i,q}) + \sum_{q=1}^{n_i} \frac{1}{2} \beta_{i,q} \Theta_{i,q}^2$

The remaining problem is now the one of handling the term $\sum_{q=1}^{n_i} \Delta_{i,q}$ in [\(22\)](#page-4-6) containing the signs of the control directions, which are unknown in view of [Assumption](#page-2-5) [1](#page-2-5). To tackle this term, a logic-based switching mechanism is proposed in the next section to adapt online the estimates $h_{i,m}$ of the multiple control directions.

4. Proposed logic-based design

Logic-based adaptation has been proposed in the literature for different classes of systems ([Huang & Yu](#page-9-29), [2018](#page-9-29); [Oliveria,](#page-9-35) [Peixoto, & Liu](#page-9-35), [2010](#page-9-35); [Wu et al.](#page-9-30), [2016](#page-9-30)). Because logic-based loops are switched systems [\(Branicky,](#page-9-36) [1998](#page-9-36); [Liberzon](#page-9-25), [2003;](#page-9-25) [Zhang,](#page-9-37) [Branicky, & Phillips](#page-9-37), [2001](#page-9-37)), the concept of solution is intended in the sense of Carathéodory ([Liberzon,](#page-9-25) [2003,](#page-9-25) Sect. 1.2.1). Also, the subsequent switching mechanism is designed in such a way that chattering is avoided and the switching stops in finite time. Therefore, phenomena such as sliding mode or Zeno behavior, which are often a concern in switched systems, are avoided.

4.1. Switching mechanism

We adopt a similar notation to [Huang and Yu](#page-9-29) ([2018](#page-9-29)), where the vectors $\mathbf{d}_{i,\sigma} \in \mathbb{R}^{n_i}$, whose elements are either 1 or -1, are used to represent all possible combinations of *nⁱ* control directions for each agent *i*. Accordingly, the switching sequence $\sigma(\cdot)$, taking values in 0, 1, ..., 2^{n_i} - 1, is a piecewise rightcontinuous function [\(Liberzon](#page-9-25), [2003,](#page-9-25) Chap.1), and goes through all such possible combinations. For example, if $n_i = 2$, we have four possible combinations: $d_{i,0} = [-1, -1]^T$, $d_{i,1} = [-1, 1]^T$, $d_{i,2} = [1, 1]^T$, $d_{i,3} = [1, -1]^T$. The order according to which the combinations are listed can be arbitrary, provided that all

Algorithm 1 Logic-Based Distributed Switching Control Mechanism for the *i*th Follower Agent

- 1: **Initialize:** Set $t_0 \leftarrow 0$, $\sigma \leftarrow 0$, $h_i(t_0) \leftarrow d_{i,0}$, $\overline{V}_i(t_0) \geq \ell_{i,\infty}(t_0) > 0$ and $\overline{V}_i(t_0) \geq \widehat{V}_{i,n_i}(t_0)$. Select positive design parameters $\zeta_{\ell_{i,\infty}}$ and $\zeta_{k_{i,m}}, i = 1, \ldots, N, m = 1, \ldots, n_i.$
- 2: For every time *t*, for every agent *i*, calculate $V_{i,n_i}(t)$, $\ell_i(t_{\sigma}, t)$, $V_i(t)$, $\ell_i(t_{\sigma}, t)$ and $\ell_i(t_{\sigma}, t)$ $L_i(t_\sigma, t)$, and $M_i(t_\sigma, t)$.
- 3: **while** $(\mathcal{M}_i(t_\sigma, t) \geq 0)$, **do** 4: Implement virtual control law (9), actual control 5: law (10), and parameter adaptation law (11). 6: $\mathbf{h}_i(t) \leftarrow \mathbf{d}_{i,\sigma};$
7: $\ell_{i,\infty}(t) \leftarrow \ell_{i,\sigma}$ $\ell_{i,\infty}(t) \leftarrow \ell_{i,\infty}(t_{\sigma});$ 8: $k_{i,m}(t) \leftarrow k_{i,m}(t_{\sigma});$ 9: else 10: $\sigma \leftarrow \sigma + 1;$
11: if σ 11: if σ is equal to 2^{n_i} ; 12: then $\sigma \leftarrow 0$: 13: end if 14: $t_{\sigma} \leftarrow t$; 15: $\overline{V}_i(t_\sigma) \leftarrow \max\left\{\widehat{V}_{i,n_i}(t_\sigma^-), \widehat{V}_{i,n_i}(t_\sigma)\right\};$ 16: $h_i(t) \leftarrow d_{i,\sigma}$; 17: $\ell_{i,\infty}(t_{\sigma}) \leftarrow \ell_{i,\infty}(t_{\sigma-1}) + \zeta_{\ell_{i,\infty}};$

18: $\ell_{i,\infty}(t) \leftarrow \ell_{i,\infty}(t_{\sigma})$: $\ell_{i,\infty}(t) \leftarrow \ell_{i,\infty}(t_{\sigma});$ 19: $k_{i,m}(t_{\sigma}) \leftarrow k_{i,m}(t_{\sigma-1}) + \zeta_{k_{i,m}};$

20: $k_{i,m}(t) \leftarrow k_{i,m}(t_{\sigma}).$ 21: **end while**

combinations are listed without repetitions. The reader can refer to [Huang and Yu](#page-9-29) ([2018\)](#page-9-29) for more details on *di*,σ . Please notice that each agent can exhibit its own switching sequence σ*i*(·): however, in the following we will simply use $\sigma(\cdot)$ to avoid complicating the notation. Define **with** $h_{i,m} ∈ {−1, 1}$ **,** $m = 1, \ldots, n_i$. Let us now define

$$
\overline{V}_i(t) = \max \Big\{ \ell_i(t_\sigma, t), \ \widehat{V}_{i, n_i}(t) \Big\},\tag{23}
$$

$$
\mathcal{L}_i(t_\sigma, t) = \ell_i(t_\sigma, t) - \overline{V}_i(t), \qquad (24)
$$

with

$$
\widehat{V}_{i,n_i} = \sum_{m=1}^{n_i} \left\{ \frac{\vartheta_{i,m}^{p_i-p_{i,m}+4}}{p_i - p_{i,m} + 4} + \frac{1}{2\gamma_{i,m}} \widehat{\Theta}_{i,m}^2 \right\}
$$
(25)

and $\ell_i(t_\sigma, t)$ being a dynamic boundary function designed as

$$
\ell_i(t_\sigma, t) = (\overline{V}_i(t_\sigma) - \ell_{i,\infty}(t_\sigma)) \exp(-\theta_i(t - t_\sigma)) + \ell_{i,\infty}(t_\sigma),
$$

where $\theta_i > 0$ is a design parameter. Let

$$
\mathcal{M}_i(t_\sigma, t) = \mathcal{L}_i(t_\sigma, t) + \kappa_i \tag{26}
$$

where $\kappa_i > 0$ is a preselected constant.

We are now in a position to present the logic-based mechanism for updating $h_i(t)$, $\sigma(t)$, $k_{i,m}(t)$, $m = 1, \ldots, n_i$, and $\ell_{i,\infty}(t)$. After an initialization phase, the mechanism comprises a hold phase (i.e. σ is kept constant) and an update phase (i.e. σ is switched to a new value).

 \bm{I} nitialization: t_0 ← $\bm{0},$ σ ← $0,$ $\bm{h}_i(t_0)$ ← $\bm{d}_{i,0},$ $\overline{V}_i(t_0)$ \geq $\ell_{i,\infty}(t_0) > 0$ and $\overline{V}_i(t_0) \geq \widehat{V}_{i,n_i}(t_0)$.
 Used where: Phase in between

Hold phase: Phase in-between consecutive switching instants:

$$
\text{while} \qquad \mathcal{M}_i(t_\sigma, t) \geq 0, \tag{27}
$$

$$
\mathbf{d}\mathbf{o} \qquad \qquad \mathbf{h}_i(t) \leftarrow \mathbf{d}_{i,\sigma}; \tag{28}
$$

$$
\ell_{i,\infty}(t) \leftarrow \ell_{i,\infty}(t_{\sigma});\tag{29}
$$

$$
k_{i,m}(t) \leftarrow k_{i,m}(t_{\sigma});\tag{30}
$$

end while

at the same time, implement virtual control law (9) , actual control law [\(10](#page-3-9)), and parameter adaptation law [\(11\)](#page-3-1). *Update phase*: Phase at the switching instant:

if
$$
\mathcal{M}_i(t_\sigma, t) < 0,
$$
 (31)

then
$$
\sigma \leftarrow \sigma + 1;
$$
 (32)

if σ is equal to 2^{n_i} , then $\sigma \leftarrow 0$: (33)

end if

$$
t_{\sigma} \leftarrow t; \tag{34}
$$

$$
\overline{V}_{i}(t_{\sigma}) \leftarrow \max\left\{\widehat{V}_{i,n_{i}}(t_{\sigma}^{-}), \widehat{V}_{i,n_{i}}(t_{\sigma})\right\};\tag{35}
$$

$$
\boldsymbol{h}_i(t) \leftarrow \boldsymbol{d}_{i,\sigma};\tag{36}
$$

$$
\ell_{i,\infty}(t_{\sigma}) \leftarrow \ell_{i,\infty}(t_{\sigma-1}) + \zeta_{\ell_{i,\infty}};
$$
\n(37)

$$
\ell_{i,\infty}(t) \leftarrow \ell_{i,\infty}(t_{\sigma});\tag{38}
$$

$$
k_{i,m}(t_{\sigma}) \leftarrow k_{i,m}(t_{\sigma-1}) + \zeta_{k_{i,m}};
$$
\n(39)

$$
k_{i,m}(t) \leftarrow k_{i,m}(t_{\sigma});\tag{40}
$$

end if

with $\zeta_{\ell_{i,\infty}} > 0$ and $\zeta_{k_{i,m}} > 0$ being design constants, $m =$ $1, \ldots, n_i, \sigma = 1, 2, \ldots$, and where t_{σ} denotes the value of t_{σ} when ([31](#page-5-2)) is satisfied but $h_i(t_\sigma)$, $\ell_{i,\infty}(t_\sigma)$, and $k_{i,m}(t_\sigma)$ have not been updated yet, and t_{σ} represents the time instant when [\(31\)](#page-5-2) holds, and in the meantime, $h_i(t_\sigma)$, $\ell_{i,\infty}(t_\sigma)$, and $k_{i,m}(t_\sigma)$ also have been updated according to $(36)-(40)$ $(36)-(40)$ $(36)-(40)$ $(36)-(40)$.

The rationale for the proposed mechanism is as follows: the switching instants t_{σ} , $\sigma = 0, 1, \ldots$, occur whenever condition (31) (31) (31) is satisfied. The reset condition in (33) is necessary when all combinations in $\mathbf{d}_{i\sigma}$ have been visited and thus it is necessary to start from the first one. The logic condition ([35\)](#page-5-6) circumvents the chattering phenomena at the switching instants *t_σ*, as elaborated in [Remark](#page-5-1) [4.](#page-5-1)

The unique challenges of using logic-based mechanisms to handle multiple unknown control directions for power-chained form are elaborated in the following remarks:

Remark 3. A crucial challenge of the proposed logic-based switching is that the exact value of the Lyapunov function $V_{i,m}$ ([18](#page-4-7)) is unavailable (as it contains the unknown constants $\Theta_{i,m}$ in $\Theta_{i,m} = \Theta_{i,m} - \widehat{\Theta}_{i,m}$). Therefore, the unavailable Lyapunov function must be replaced by some estimate. To pursue this, the Lyapunovlike function V_{i,n_i} ([25](#page-5-7)) is proposed and designed in such a way as to establish the boundedness of the closed-loop signals (cf. appendix).

Remark 4. State-of-the-art logic-based mechanisms ([Cui, Huang,](#page-9-38) [& Gao](#page-9-38), [2020](#page-9-38); [Huang & Yu,](#page-9-29) [2018;](#page-9-29) [Wu et al.](#page-9-30), [2016](#page-9-30)) cannot formally exclude chattering phenomena since they adopt $\ell_i(t_\sigma, t_\sigma)$ = $\overline{V}_i(t_\sigma) = \widehat{V}_{i,n_i}(t_\sigma) = \widehat{V}_{i,n_i}(t_\sigma^-)$. More precisely, the update phase of [Cui et al.](#page-9-38) [\(2020\)](#page-9-38), [Huang and Yu](#page-9-29) ([2018\)](#page-9-29) and [Wu et al.](#page-9-30) ([2016\)](#page-9-30) is designed as

$$
\text{if} \qquad \qquad \mathcal{M}_i(t_\sigma,t) < 0,
$$

then
$$
t_{\sigma} \leftarrow t
$$
;
\n
$$
\overline{V}_{i}(t_{\sigma}) \leftarrow \widehat{V}_{i,n_{i}}(t_{\sigma}^{-});
$$
\n
$$
\mathbf{h}_{i}(t) \leftarrow \mathbf{d}_{i,\sigma};
$$
\n
$$
k_{i,m}(t_{\sigma}) \leftarrow k_{i,m}(t_{\sigma-1}) + \zeta_{k_{i,m}};
$$

end if

In view of the discussions in Ye ([2005](#page-9-28), Remark 2 and the analysis after Eq. (35)), it is theoretically possible for such mechanisms

to yield an increase $\overline{V}_i(t_\sigma) = \hat{V}_{i,n_i}(t_\sigma) > \hat{V}_{i,n_i}(t_\sigma^+) + \kappa_i =$ $\ell_i(t_\sigma, t_\sigma) + \kappa_i$, which indicates that $M_i(t_\sigma, t) < 0$, leading to a new switching instant immediately after the previous one. This is because updating $h_i(t)$ and $k_{i,m}$ may result in instantaneous changes in the tracking errors $\vartheta_{i,m}$, according to ([7\)](#page-3-7)–[\(10](#page-3-9)), which may lead to an increase of the value of the Lyapunov functions (13) (13) (13) , (18) (18) (18) , and (20) (20) (20) . This could make the inequality (31) (31) (31) hold once more immediately after the previous time instant. To solve such issue, we exclude chattering phenomena by proposing a new dynamic threshold condition [\(35\)](#page-5-6) at the switching instants, based on selecting the maximum values of the Lyapunov-like function before and after switching.

Remark 5. State-of-the-art logic-based designs for strictfeedback systems [\(Cui et al.](#page-9-38), [2020](#page-9-38); [Huang & Yu,](#page-9-29) [2018;](#page-9-29) [Wu et al.,](#page-9-30) [2016\)](#page-9-30) rely on the fact that asymptotic tracking can be obtained for this class of systems: there exists at least one $d_{i,\sigma}$, $\sigma \in$ $\{0, 1, \ldots, 2^{n_i} - 1\}$, that leads to a vanishing tracking error. Unfortunately, it is well known in the literature that asymptotic tracking is impossible in general for the class of nonlinear systems ([1](#page-2-1)) [\(Qian & Lin](#page-9-11), [2002](#page-9-11)). Therefore, the switching logic cannot rely on vanishing tracking errors. To overcome the above difficulty, we propose a new monitor function $\ell_i(\cdot)$, which is decreasing inbetween switching instants and possibly increasing at switching instants. The role of $\ell_i(\cdot)$ is crucial to closed-loop stability through ([23](#page-5-8)): $\ell_i(\cdot)$ is used to monitor the upper bound of the designed Lyapunov-like function V_{i,n_i} as shown in [Fig.](#page-2-0) [1.](#page-2-0) The distinguishing
facture of $\ell(\cdot)$ is the allow \widehat{V} at a increase have appropriate the feature of $\ell_i(\cdot)$ is to allow \widehat{V}_{i,n_i} to increase by a constant at every quitable probability in the finite quitables most every switching instant. Notice that the finite-switching mechanism guarantees that $\ell_i(\cdot)$ does not grow to infinity and thus closed-loop stability can be obtained.

4.2. Main stability result

To analyze the stability of the closed-loop system, we consider the global Lyapunov function

$$
V = \sum_{i=1}^{N} V_{i,n_i}, \text{ and } \widehat{V} = \sum_{i=1}^{N} \widehat{V}_{i,n_i}
$$
 (41)

Fig. 2. Two different communication topologies.

5. Simulation results

To validate the effectiveness of the proposed control method, two different communication topologies with one leader (labeled by 0) and three follower agents are considered as represented by the directed graph of [Fig.](#page-6-1) [2](#page-6-1). From Fig. 2-(a) and $-(b)$, it can be seen that the signal of the leader is only accessible to follower 1 and follower 2, respectively. The following parameter settings are kept the same for both topologies. The leader output is $v_r =$ $6 \sin(0.5t) + 6 \sin(t)$ and the three follower agents are described by the following dynamics:

Agent 1

\n
$$
\begin{cases}\n\dot{\chi}_{1,1} = 1.5 \cos(\chi_{1,1}) \chi_{1,1} + 0.8 \chi_{1,2}^3, \\
\dot{\chi}_{1,2} = \chi_{1,1} \sin(\chi_{1,2}) + (\tanh(\chi_{1,1}) + 1.2) u_1^5.\n\end{cases}
$$
\n
$$
\begin{cases}\n\dot{\chi}_{2,1} = 1.25 \chi_{2,1} + 0.5 \chi^3 + 1.5 \chi^3\n\end{cases}
$$

Agent 2
$$
\begin{cases} \dot{\chi}_{2,1} = 1.25 \chi_{2,1} + 0.5 \chi_{2,1}^3 + 1.5 \chi_{2,2}^3, \\ \dot{\chi}_{2,2} = 0.75 \chi_{2,2} \chi_{2,1}^2 + (\sin(\chi_{2,1})^2 + 0.75) u_2^5 \end{cases}
$$

Agent 3
$$
\begin{cases} \dot{\chi}_{3,1} = 0.5(\cos(\chi_{3,1}) + \chi_{3,1}^2) + 1.2\chi_{3,2}^3, \\ \dot{\chi}_{3,2} = \chi_{3,1} \sin(\chi_{3,2}) + (|\cos(\chi_{3,1})| + 0.2)\mu_3^5. \end{cases}
$$

In our simulation, RBF NNs are used as linear-in-the-parameter approximators to approximate $|E_{i,j}(\mathbf{Z}_{i,j})|$, $i = 1, 2, 3, j = 1, 2,$ employing 64 nodes with centers evenly spaced in $[-1.5, 1.5] \times$ $[-1.5, 1.5] \times [-1.5, 1.5] \times [-1.5, 1.5] \times [-1.5, 1.5] \times [-1.5, 1.5] \times$ [−1.5, 1.5]× [−1.5, 1.5]× [−1.5, 1.5] and widths equal to 2. The initial conditions are selected as: $\chi_{1,1}(0) = 0.75$, $\chi_{1,2}(0) = -1.75$, $\chi_{2,1}(0) = 1.5, \chi_{2,2}(0) = -1.5, \chi_{3,1}(0) = 1.75, \chi_{3,2}(0) = -1.2,$ $\widehat{\Theta}_{1,1}(0) = 6.5, \widehat{\Theta}_{1,2}(0) = 7.5, \widehat{\Theta}_{2,1}(0) = 4, \widehat{\Theta}_{2,2}(0) = 3, \widehat{\Theta}_{3,1}(0) =$ 6.5, $\widehat{\Theta}_{3,2}(0) = 4.75$, $\ell_{1,\infty}(0) = \ell_{2,\infty}(0) = \ell_{3,\infty}(0) = 0.5$, $k_{1,1}(0) =$ $k_{2,1}(0) = k_{3,1}(0) = 6$, $k_{1,2}(0) = k_{2,2}(0) = k_{3,2}(0) = 8$. The design parameters are chosen as: $\zeta_{k_{1,1}} = \zeta_{k_{1,2}} = 1$, $\zeta_{k_{2,1}} = \zeta_{k_{2,2}} = \zeta_{k_{3,1}} =$ $\zeta_{k_{3,2}} = 1.5$, $\epsilon_{1,1} = \epsilon_{1,2} = \epsilon_{2,1} = \epsilon_{2,2} = \epsilon_{3,1} = \epsilon_{3,2} = 1$, $\varrho_{1,1} = \varrho_{1,2} = \varrho_{1,3} = \varrho_{1,4} = \varrho_{1,5} = \varrho_{1,6} = \varrho_{1,7} = \varrho_{1,8} = \varrho_{1,9} = \varrho_{1,1} = \varrho_{1,1} = \varrho_{1,2} = \varrho_{1,3} = \varrho_{1,4} = \varrho_{1,5} = \varrho_{1,6} = \varrho$ $\varrho_{1,2}^{\prime\prime} = \varrho_{2,1} = \varrho_{2,2} = \varrho_{3,1} = \varrho_{3,2} = 1, \gamma_{1,1} = \gamma_{2,1} = \gamma_{3,1} = 1,$ $\gamma_{1,2} = \gamma_{2,2} = \gamma_{3,2} = 0.4$, $\beta_{1,1} = \beta_{2,1} = \beta_{3,1} = 0.8$, $\beta_{1,2} = \beta_{2,2} =$ $\beta_{3,2} = 6.25, \delta_{1,1} = \delta_{2,1} = \delta_{3,1} = 0.25, \kappa_1 = \kappa_2 = \kappa_3 = 0.3,$ $\theta_1 = 1.8, \theta_2 = 1.25, \theta_3 = 0.75, \zeta_{\ell_{1,\infty}} = \zeta_{\ell_{2,\infty}} = \zeta_{\ell_{3,\infty}} = 0.5,$ $\underline{\rho}_{1,1} = \underline{\rho}_{2,1} = \underline{\rho}_{3,1} = -6, \overline{\rho}_{1,1} = \overline{\rho}_{2,1} = \overline{\rho}_{3,1} = 8, \underline{l}_{1,1} = \underline{l}_{2,1} =$ $l_{3,1} = 3$, $\overline{l}_{1,1} = \overline{l}_{2,1} = \overline{l}_{3,1} = 4$, and $\rho_{1,\infty} = \rho_{2,\infty} = \rho_{3,\infty} = 0.95$.

The simulation results are shown in [Figs.](#page-7-1) [3](#page-7-1)[–8.](#page-8-0) [Figs.](#page-7-1) [3-](#page-7-1)(a) and [5](#page-7-2)-(a) reveal that the tracking errors $\xi_{i,1}$, $i = 1, 2, 3$, under the two topologies evolve within their respective bounds. [Figs.](#page-7-1) [3](#page-7-1)-(b)–(c) and [5-](#page-7-2)(b)–(c) show that the functions \hat{V}_{i,n_i} , $i = 1, 2, 3$, under both topologies are upper bounded by ℓ , $i = 1, 2, 3$, respectively. It can topologies are upper bounded by ℓ_i , $i = 1, 2, 3$, respectively. It can be seen from [Figs.](#page-7-3) [4](#page-7-3) and [6](#page-7-4) that switching for both topologies stops in finite time and that the parameters $k_{i,j}$, $i = 1, 2, 3, j = 1, 2$, are updated synchronously with the control directions $h_{i,j}$, $i = 1, 2, 3$, $j = 1, 2$. [Figs.](#page-7-0) [7](#page-7-0) and [8](#page-8-0) show that the NN approximators can achieve satisfactory approximation (see [Fig.](#page-7-1) [3\)](#page-7-1).

6. Conclusions

This work has proposed a logic-based switching mechanism for distributed switching tracking control of nonlinear multiagent systems in power-chained form and with multiple unknown control directions. A novel dynamic boundary function

[Fig.](#page-6-1) 8. Topology in Fig. [2](#page-6-1)-(b): evolution of $|E_{1,1}|$, $|E_{1,2}|$, $|E_{2,1}|$, $|E_{2,2}|$, $|E_{3,1}|$, $|E_{3,2}|$, and their NN approximations $|\widehat{E}_{1,1}|$, $|\widehat{E}_{1,2}|$, $|\widehat{E}_{2,1}|$, $|\widehat{E}_{2,2}|$, $|\widehat{E}_{3,1}|$, $|\widehat{E}_{3,2$

that is decreasing in-between switching instants and possibly increasing at the switching instants has been devised. An interesting problem to be investigated in the future is to combine logic-based update of the control directions with logic-based update of the parameters.

Appendix

Proof of [Theorem](#page-6-2) [1](#page-6-2). We provide the proof through two stages. At stage 1, we show that the control goals of [Theorem](#page-6-2) [1](#page-6-2) are guaranteed on the interval $[0, +\infty)$ provided that the switching stops in finite time. At stage 2, we show by contradiction that indeed the switching stops in finite time.

Stage 1: Let $[0, t_s)$ be the maximum interval of the existence of the closed-loop solution, σ_s be the final switching index, and t_{σ_s} < t_s be the time instant when the final switching occurs. Combining ([23](#page-5-8)), [\(26\)](#page-5-10), ([27](#page-5-11)), and the fact that there is only a finite number of switchings, one can conclude that after the final switching (i.e. for *t* > *t*_{σs}), it holds that $L_i(t_{\sigma_s}, t) + \kappa_i \geq 0$, $t \in [t_{\sigma_s}, t_s)$, which indicates that

$$
\widehat{V}_{i,n_i}(t) \le \ell_i(t_{\sigma_s},t) + \kappa_i, \ t \in [t_{\sigma_s},t_s). \tag{42}
$$

Thus, $\widehat{V}_{i,n_i}(\cdot)$, $\vartheta_{i,m}$ and $\widehat{\Theta}_{i,m}(\cdot)$, $i = 1, \ldots, N$, $m = 1, \ldots, n_i$, org bounded due to the houndedness of $\ell(\cdot)$ and μ on the are bounded due to the boundedness of $\ell_i(\cdot)$ and κ_i on the int *i*nterval $[t_{\sigma_s}, t_s]$. Furthermore, the virtual control laws $\alpha_{i,m}$, $m =$ 1, ..., $n_i - 1$, $i = 1, ..., N$ and the actual control law u_i , $i =$ $1, \ldots, N$ are bounded on [t_{σ_s}, t_s] according to ([8\)](#page-3-2)–[\(10](#page-3-9)). Thus, $\chi_{i,m}$, $\widetilde{\Theta}_{i,m}$, $m = 1, \ldots, n_i$, $i = 1, \ldots, N$, are bounded on $[t_{\sigma_s}, t_s)$ arising
from the fact that $y(t) = 0$, and $\widehat{\Theta}_{i,j}$ (e) are hounded on $[t_{\sigma_s}, t_s]$ from the fact that $y_r(\cdot)$, $\Theta_{i,m}$, and $\widehat{\Theta}_{i,m}(\cdot)$ are bounded on $[t_{\sigma_5}, t_5]$. According to [Sontag](#page-9-39) [\(1998](#page-9-39), Theorem 54, page. 476), no finite-time escape phenomena occurs, and thus $t_s = +\infty$. As a result, one concludes that all closed-loop signals are bounded on the entire time interval [0, $+\infty$). Then, invoking [\(25](#page-5-7)) yields

$$
\lim_{t\to+\infty}|\vartheta_{i,1}|\leq \big[(p_i-p_{i,1}+4)(\ell_{i,\infty}(t_{\sigma_s})+\kappa_i)\big]^{\frac{1}{p_i-p_{i,1}+4}}\n\triangleq \overline{\vartheta}_{i,1}
$$

which, in combination with the definition of $\vartheta_{i,1}$, gives

$$
\lim_{t\to+\infty}\xi_{i,1}(t)\leq \frac{\rho_{i,\infty}\exp(\overline{\vartheta}_{i,1})-\rho_{i,\infty}}{1+\exp(\overline{\vartheta}_{i,1})}
$$

After using a lower bound $\frac{\bar{N}}{N^2+N-1}$ [\(Hong & Pan](#page-9-40), [1992](#page-9-40)) with $\bar{N} = \left(\frac{N-1}{N}\right)^{\frac{N-1}{2}}$ for $\sigma_{\min}(\overline{\mathscr{L}} + \mathscr{B})$, it follows that

$$
\lim_{t\to+\infty}||\omega(t)|| \leq \sqrt{\frac{(N^2+N-1)^2\sum_{i=1}^N\frac{\rho_{i,\infty}^2[(\exp(\overline{\vartheta}_{i,1})-1)]^2}{[1+\exp(\overline{\vartheta}_{i,1})]^2}}{N^{1-N}(N-1)^{N-1}}}.
$$

We are now in a position to discuss the existence of a compact set that makes the universal approximation ability valid, provided that the switching stops in finite time.

Consider the initial conditions $\bar{\chi}_{i,m}(0)$ and $\widehat{\Theta}_{i,m}(0) \geq 0$, for $i =$ 1, ..., *N*, $m = 1, ..., n_i$, satisfying $\widehat{V}(\overline{\chi}_{i,m}(0), \widehat{\Theta}_{i,m}(0)) < \Upsilon_0$ with

 $\gamma_0 = \sum_{i=1}^N \hbar_i$ with $\hbar_i \triangleq \max_{\sigma \in \{0,1,\dots,\sigma_S\}} \ell_i(t_\sigma, t_\sigma)$ and consider the compact set

$$
\Omega_0 = \left\{ \left(\overline{\chi}_{i,m}(t), \widehat{\Theta}_{i,m}(t) \right) \middle| \widehat{V} \left(\overline{\chi}_{i,m}, \widehat{\Theta}_{i,m} \right) \leq \varUpsilon, \ t \geq 0 \right\}
$$
(43)

where $\Upsilon = \Upsilon_0 + \sum_{i=1}^{N} \kappa_i$. According to Algorithm [1,](#page-5-9) [\(41\)](#page-6-3), and [\(42\)](#page-8-2), \hbar ^{*i*} is bounded provided that the switching stops in finite time, and that the inequality

$$
\widehat{V}\big(\overline{\chi}_{i,m}(t),\widehat{\Theta}_{i,m}(t)\big)<\Upsilon,\tag{44}
$$

holds true for all $t \ge 0$ provided that $\widehat{V}(\overline{\chi}_{i,m}(0), \widehat{\Theta}_{i,m}(0)) <$
 $\widehat{\chi}$, holds true Therefore, the evictors of the compact set $\widehat{\Omega}$ γ_0 holds true. Therefore, the existence of the compact set Ω_0 makes the universal approximation ability of the linear-in-theparameter approximation valid since all state variables involved are retained in Ω_0 all the time.

Stage 2: At this stage, by seeking a contradiction, we prove that there indeed exist a finite number of switchings. Let us first suppose that there exist an infinite number of switchings. Therefore, there surely exists a sufficiently large t_{σ_s} such that

$$
\gamma_{i,q}\beta_{i,q} \leq (p_i - p_{i,q} + 4)c_{i,q}\eta_i^{\frac{p_{i,q}-1}{p_i+3}}, i = 1, ..., N, q = 1, ..., n_i,
$$

and such that

$$
\boldsymbol{h}_i(t) = \boldsymbol{d}_{i,\sigma_s} = \left[sign(\psi_{i,1}), \ldots, sign(\psi_{i,n_i}) \right]^T
$$
\n(45)

on $[t_{\sigma_s}, t_{\sigma_s+1})$. Thus, $\zeta_i = \gamma_{i,q} \beta_{i,q}, q = 1, ..., n_i, i = 1, ..., N$. It follows from (43) (43) (43) that (22) (22) becomes

$$
\dot{V}_{i,n_i} < -\varsigma_i V_{i,n_i} + \varXi_i \quad \text{as} \quad \sum_{q=1}^{n_i} \varDelta_{i,q} = 0,\tag{46}
$$

which, combined with ([20](#page-4-8)) and the Gronwall inequality [\(Qian &](#page-9-11) [Lin](#page-9-11), [2002](#page-9-11)), implies that

$$
\vartheta_{i,m}^{p_i+3} < \left[(p_i-p_{i,m}+4)(V_{i,n_i}(0)+\mathcal{Z}_i/\varsigma_i) \right]^{\frac{p_i+3}{p_i-p_{i,m}+4}} \triangleq \Psi_{i,m}
$$

$$
\left|\widehat{\Theta}_{i,m}\right| < \sqrt{2\gamma_{i,m}\big(V_{i,n_i}(0) + \mathcal{E}_i/\varsigma_i\big)} + \Theta_{i,m} \triangleq \bar{\Lambda}_{i,m} \tag{47}
$$

holds on $[t_{\sigma_s}, t_{\sigma_s+1})$ for $i = 1, ..., N$, $m = 1, ..., n_i$. Thus, it follows from ([11](#page-3-1)) that

$$
\left|\widehat{\Theta}_{i,m}\right| < \gamma_{i,m}\epsilon_{i,m}^{\overline{p}_{i,m}}\Psi_{i,m}\overline{\Gamma}_{i,m} + \gamma_{i,m}\beta_{i,m}\overline{\Lambda}_{i,m} \triangleq \gamma_{i,m} \tag{48}
$$

holds on $[t_{\sigma_s}, t_{\sigma_s+1})$, where $\overline{\Gamma}_{i,m}$ is the upper bound of $\Gamma_{i,m}^{\overline{p}_{i,m}}$ according to [Zhao et al.](#page-9-16) ([2016,](#page-9-16) Lemma 2), for $i = 1, ..., N$, $m = 1, \ldots, n_i$.

Recalling (20) , (25) (25) (25) , (46) (46) – (48) (48) , we can obtain that

$$
\hat{V}_{i,n_i}(t) < -\varsigma_i V_{i,n_i} + \Xi_i + \sum_{m=1}^{n_i} \frac{\Theta_{i,m} \hat{\Theta}_{i,m}}{\gamma_{i,m}}
$$
\n
$$
\langle -\varsigma_i \hat{V}_{i,n_i} + \Xi_i + \sum_{m=1}^{n_i} \frac{\Theta_{i,m} \hat{\Theta}_{i,m}}{\gamma_{i,m}} - \sum_{m=1}^{n_i} \frac{\varsigma_i \Theta_{i,m}^2}{2\gamma_{i,m}}
$$
\n
$$
+ \sum_{m=1}^{n_i} \frac{\varsigma_i \Theta_{i,m} \hat{\Theta}_{i,m}}{\gamma_{i,m}} < -\varsigma_i \hat{V}_{i,n_i} + \widehat{\Xi}_i,\tag{49}
$$

where $\widehat{\mathcal{Z}}_i = \mathcal{Z}_i + \sum_{m=1}^{n_i} \frac{\Theta_{i,m} \gamma_{i,m}}{\gamma_{i,m}}$ $\frac{\sum_{j \in \mathcal{N}} m_i}{\sum_{j \in \mathcal{N}} m_j} + \sum_{j \in \mathcal{N}} n_i}$ *i* s a positive constant. Hence, we have $\widehat{V}_{i,n_i}(t) \leq \frac{\widetilde{S}_i}{\varsigma_i}$, on $[t^*, t_{\sigma_s+1})$, where t^* is the first time instant satisfying $\widehat{V}_{i,n_i}(t^*) = \frac{\widehat{z}_i}{s_i}$. Then, $\widehat{V}_{i,n_i} < 0$ holds when $\widehat{V}_{i,n_i} \geq \frac{S_i}{S_i}$. The fact that $\widehat{V}_{i,n_i}(\cdot)$ strictly decreases on the time interval $[t_{\sigma_s}^{s_t}, t^*)$ implies that no new switching occurs on $[t_{\sigma_s}, t^*)$ and that $t^* < t_{\sigma_s+1}$.

When $t \in [t_{\sigma_s}, t^*)$, we can guarantee $0 < \theta_i \leq \varsigma_i$ by choosing proper $\gamma_{i,q}$, and $\beta_{i,q}$, $q = 1, \ldots, n_i$, according to $\zeta_i = \gamma_{i,q} \beta_{i,q}$, $q =$ 1, ..., n_i , $i = 1, ..., N$, which implies that $\hat{V}_{i, n_i}(t) \leq \ell_i(t)$, on $[t_{\sigma_s}, t^*]$. When $t \in [t^*, t_{\sigma_s+1})$, the condition $\ell_{i,\infty}(t) \geq \frac{S_i}{S_i}$ can be satisfied via a sufficiently large $\sigma_{\rm s}$ in view of [\(29](#page-5-12)) and ([30\)](#page-5-13). Hence, it holds that $\widehat{V}_{i,n_i}(t) \leq \ell_i(t_{\sigma_s}, t)$, $\forall t \in [t^*, t_{\sigma_s+1})$.

To summarize, we have that $\widehat{V}_{i,n_i}(t) < \ell_i(t_{\sigma_s}, t) < \ell_i(t_{\sigma_s}, t) + \kappa_i$
 $\left\{t_{\sigma_s}, t_{\sigma_s}, t_{\sigma_s}\right\}$ on $[t_{\sigma_s}, t_{\sigma_s+1})$, which means that switching condition ([31](#page-5-2)) can never be satisfied on the time interval $[t_{\sigma_{s}}, t_{\sigma_{s}+1})$. This contradicts the assumption made in the beginning of stage 2. Thus, the proof is completed. ■

Maolong Lv received the B.Sc. and M.Sc. from Air Force Engineering University, Xi'an, China, in 2014, and 2016 respectively, and the Ph.D. at Delft Center for Systems and Control, Delft University of Technology, The Netherlands, in 2021. He is currently with College of Air Traffic Control and Navigation, Air Force Engineering University. His research interests include adaptive learning control, deep reinforcement learning, distributed control, and intelligent decision-making with applications in multi-agent systems, hypersonic vehicles, unmanned autonomous systems. Dr. Lv was

awarded a Descartes Excellence Fellowship from the French Government in 2018, which allowed him a research visit from 2018 to 2019 at University of Grenoble working on adaptive networked systems with emphasis on traffic with human driven and autonomous vehicles.

Bart De Schutter received his Ph.D. (summa cum laude) in applied sciences in 1996 at Katholieke Universiteit (KU) Leuven, Belgium. He is full professor and department head of Delft Center for Systems and Control at Delft University of Technology, The Netherlands. He is (co-)author of three books, *Optimal Trajectory Planning and Train Scheduling for Urban Rail Transit Systems*, *Reinforcement Learning and Dynamic Programming Using Function Approximators*, *Stability Analysis and Nonlinear Observer Design Using Takagi–Sugeno Fuzzy Models*, and of more than 200 papers in international journals. Prof. De Schutter was Associate Editor of *Automatica* in 2004–2016 and he is currently Associate Editor of *IEEE Trans. on Automatic Control*, and Senior Editor of *IEEE Trans. on Intelligent Transportation Systems*. He is *IEEE Fellow*.

Chao Shi received the B.Sc. in information countermeasure from the Nanjing University of Science and Technology, Nanjing, China, in 2012, and the M.Sc. and Ph.D. from Air Force Engineering University, Xi'an, China, in 2014, and 2018 respectively. His current research interests include deep reinforcement learning, flight control, and adaptive learning control.

Simone Baldi received the B.Sc. in electrical engineering, and the M.Sc. and Ph.D. in automatic control engineering from University of Florence, Italy, in 2005, 2007, and 2011. He is professor at School of Mathematics, Southeast University, with guest position at Delft Center for Systems and Control, TU Delft, where he was assistant professor. He was awarded outstanding reviewer of *Automatica* for 2017. He is subject editor of *International Journal of Adaptive Control and Signal Processing* and associate editor of *IEEE Control Systems Letters*. His research interests include adaptive and

switched systems with applications in networked and multi-agent control.
